tellectual was to be a student of Confucianism, a body of writings and commentary that for two millennia had been the focus of education and scholarly endeavor. Since the sixth century CE, Confucianism also was the material on which students were tested as part of China's civil service examination system, through which successful candidates gained access to positions in the imperial bureaucracy ranging from offices in local districts to the inner circles of the imperial court. In such roles China's Confucian scholar-officials had successfully maintained China's position as the center of Asian civilization, and their success engendered strong feelings of Chinese superiority. Such smugness, along with Confucianism's inherent conservatism, made it difficult for the Chinese to respond to the Western challenge with the decisiveness of the Japanese or the openness of India's Hindus.

The long reign of Emperor Qianlong (r. 1735–1796) had been a glorious time for Chinese economic and political fortunes and for Confucian scholarly endeavors, but at the end of the reign and in the early nineteenth century a number of Confucians were disquieted by evidence of corruption and other signs of dynastic decline. In response, some searched “new texts” to find meaning relevant to China's political problems, others shifted their attention from speculative philosophy to current needs and administrative principles, while still others reflected on the possibility of change within a Confucian context. The inadequacy of such strategies was fully revealed by midcentury rebellions and a string of military defeats. Until the late 1890s, most intellectuals sought China's revival through a strategy of self-strengthening, based on selective borrowing of Western technology, especially weaponry, and the restoration of sound Confucian government by reforming the civil service examinations, reopening Confucian academies, reprinting Confucian texts, and directing scholarly activity to practical questions. Only after another military defeat (this time to Japan) in 1895, the failure of the One Hundred Days Reform in 1898, and the suppression of the Boxer Rebellion 1901 did scholars inside and outside of government conclude that saving China was more important than saving Confucianism. They threw their support behind plans to revamp the Chinese educational system along Western lines, introduce constitutional government, reorganize

Although Abduh was an Egyptian and Jamal-ad-Din was by birth a Persian, their writings addressed all Muslims, urging them to resist European imperialism but only after Islam had come to terms with modern science and rationalism.

the military, and reform the administration. A decisive step was taken in 1905 when the civil service examination system, which for centuries had guaranteed the supremacy of the Confucian-trained elite, was scrapped. Whether the government's program could have replicated Japan's transformation in the Meiji era is impossible to know. In 1911 a revolution led by nationalist army officers overthrew the Manchu emperor, and this time the mandate of heaven was not passed on to a new dynasty. China's imperial age had ended. Chinese intellectuals along with their

countrymen faced an uncertain future without the guidance of Confucianism, rule by scholar-officials, and the authority of the emperor.

The intellectuals of China were not the only ones whose assumptions and values were shaken in the twentieth century. Two fearsome world wars, economic collapse in the 1930s, revolution in Russia, the horrors of the Holocaust, and the obliteration of Hiroshima and Nagasaki by atomic weapons ensured that this would be the case.

■ Introduction: Islam

In many respects, the years between 1750 and 1900 brought nothing but disaster for the worldwide Muslim community. By the mid-eighteenth century, of the three once-powerful Islamic states of the early modern era, Safavid Persia had been overrun, the Mughal empire in India was disintegrating, and the Ottoman empire was falling behind the West militarily and economically. In the following decades Western imperialists took advantage of Muslim political weakness so that by 1900, 80 percent of all Muslims—approximately 161 million believers—lived under the political control of some Western power. Of the two major independent Islamic states, both Qajar Persia and the Ottoman empire had been forced to accept the presence of Christian missionaries, extensive European investment in their economies, and foreign control of their finances. In 1895 the Moroccan historian Ahmad ibn Khalid al-Nasiri al-Salawi wrote the following:

It is known that at this moment the Christians have reached the apogee of their strength, and that the Muslims—may God lead them together and put them on the right track—are as weak and disorderly as they could be. We are, they and we, like two birds, one with wings, who can go wherever he pleases, the other with clipped wings who keeps falling back to earth without being able to fly.

Throughout these difficult decades, there is no sign that Islam lost its vitality or its centrality in the lives of its followers. It remained the prism through which intellectuals and political leaders sought to understand the reasons for the Muslim world's declining fortunes. It also provided guidance and inspiration for revival and renewal. The result was an extraordinary period in the history of the faith, one marked by intellectual ferment, new perspectives, frequent controversy, the appearance of charismatic leaders, and the proliferation of reform movements. No part of the Islamic world was unaffected.

Throughout Muslim history, there always have been individuals and groups who took it upon themselves to reform the community. Reform movements varied in terms of inspiration, leadership, and methods, but all of them were oriented toward the past in that they sought to restore legal principles, beliefs, and rituals modeled on practices established by Muhammad and the earliest Muslim community. Many also sought to restore the early uncorrupted Muslim state in the face of perceived threats of pagan backsliding or non-Muslim rule. Some resorted to jihad, or holy war, to achieve their goals.

The eighteenth and nineteenth centuries saw a number of reform movements that resembled earlier efforts of renewal and therefore are referred to as examples of “traditional” or even “archaic” reform. At first they were primarily

related to local circumstances and had little to do with the impact of the West, but as the nineteenth century unfolded, efforts to restore pristine forms of Islam were frequently linked to resistance to European colonialists.

An early example of traditional reform is provided by the movement inspired by the Indian scholar Shah Wali Allah (1703–1762), whose many writings called for the revival of Indian Muslim learning the end of divisions among Muslims and the purification of Islamic practices. Better-known traditional reform movements took place in Arabia and West Africa. In Arabia, Muhammad Ibn Abd al-Wahhab (1703–1792) denounced other Muslims for “polytheism” and their devotion to forms of piety such as saint worship and veneration of saints’ tombs. Supported by a local Arab tribal chief, the Wahhabis took control of Medina and Mecca in the early 1800s before being expelled by an Egyptian army dispatched to the region by the Ottoman sultan. Equally important was the jihadist movement inspired by the West African scholar Usman dan Fodio (1754–1817). Deeply disturbed by the corruption and halfhearted devotion to Islam exhibited by the region’s rulers, he inspired a series of holy wars that led to the establishment of the Sokoto Caliphate in the northern part of present-day Nigeria. His example inspired several other jihadist movements that redrew the political and religious map of Sudanic Africa in the 1800s.

As the nineteenth century progressed, a number of traditionalist Islamic reform movements inspired resistance to colonial rule. In North Africa, the scholarly reformer ‘Abd al-Qadir (1808–1883) led the resistance to French rule in the 1830s and 1840s until he was defeated and forced into exile in 1847. Several other anticolonial movements were led by self-styled *mahdis*, divinely chosen individuals who aimed to restore the original purity of the Islamic faith and polity. In Sudan, Muhammad Ahmad (1884–1885) proclaimed himself Mahdi in 1881, promising to purify Islamic belief and practice while resisting oppressive practices of Egyptian and then British administrators. He died, probably of typhus, in 1885, but his Mahdist state survived until its army was overwhelmed by a British force in 1898. In other areas, Islamic reformers led resistance movements against Dutch rule in

Java and Aceh and Russian rule in the Caucasus and Inner Asia.

In contrast to traditionalist reformers, all of whom sought to restore religious practices of Islam’s early decades, Islamic modernists sought another path to revival. Like the traditionalists, they venerated the Muslim intellectual tradition but were committed to reconciling this tradition with distinctly modern values emanating from the West. These values included constitutionalism, scientific investigation, modern-style education, women’s rights, freedom of religious interpretation, and reason as a basis for intellectual judgment. These modernists were not secularists; they did not seek to eliminate the role of Islam from law and public life. They were convinced, however, that Islam had a bleak future unless it accommodated itself to certain modern, that is, Western ideas and values. Unlike traditionalist reform movements, which drew their leadership mainly from scholars or leaders of Sufi religious orders, Islamic modernists also included journalists, government officials, and former military men, many of whom had studied or traveled in Europe.

The best-known Islamic modernist was Sayyid Jamal ad-Din al-Afghani (1838–1897), who traveled across much of the Middle East and northern Africa advocating educational reform, the adoption of modern science by Muslims, and the unity of all Muslims under a single state. Al-Afghani’s disciple, Mohammad Abduh (1849–1905), devised plans for the reform of Egypt’s schools, the Arabic language, the education of girls, and the curriculum at Al-Azhar, the center for advanced Islamic studies in Cairo. In India the aristocratic Ahmad Khan (1817–1898), disturbed by the perceived backwardness of Muslims in the eyes of British officials and many educated Hindus, founded the Muhammadan Anglo-Oriental College at Aligarh, which offered courses in English on European arts and sciences in addition to Islamic studies. Its goal was to educate Indian Muslims capable of finding positions in the Indian Civil Service.

These and other Islamic modernists sought to achieve a balance between revelation and reason, tradition and innovation and religion and science. Their many critics warned of the dangers of such compromises, which they feared

would open the door to secularism and a weakening of the faith. Their worst fears seemed to be confirmed in the 1920s, when Turkey's nationalist leader Mustafa Kemal aggressively attacked reduced Islam's role in public life. As the twentieth century unfolded, however, it became clear that for many Muslims the centuries-old goal of achieving pure Islamic societies based on timeless ancient practices had lost none of its appeal.

Origins and Early History of Wahhabism

Wahhabism—the Islamic movement founded by Muhammad Ibn Abd al-Wahhab—emerged in the oases of central Arabia in the mid-1700s. Its followers prefer to be referred to as Monotheists or Unitarians, as its central tenet is a definition of monotheism that explicitly excludes popular religious practices such as Sufism and devotion to saints. Its conditional sanction of attacks upon individuals who engage in these practices contributed significantly to the rise of three emirates under the leadership of the Saud family.

Muhammad Ibn Abd al-Wahhab was born in the early 1700s in the central Arabian town of Uyayna in Najd into a family of religious scholars. He returned to Najd after studying and preaching abroad, possibly in the Hijaz and Iraq, and began his religious revival in earnest after his father's death in 1740.

In Abd al-Wahhab's view, most Muslims were ignorant of proper Islamic practice and morality. Declaring one's faith in a single God was not enough to make one a Muslim; anyone engaged in practices that drew religious devotion away from God was an idolater and open to attack. Seeking help or intercession from anyone other than God (including angels, prophets, saints, or inanimate objects) was not acceptable in his eyes, which led to condemnation of Sufis and Shias, for whom making pilgrimages to saints' tombs was an important part of their religious devotion. Most significant for the subsequent spread of the movement was the teaching that

➤ IBN ABD AL-WAHHAB'S USE OF ISLAMIC TEXTS

The following excerpt is from the first chapter of Muhammad Ibn Abd al-Wahhab's treatise on monotheism, *Kitab al-Tawhid* (The Book of God's Oneness). The book's chapters begin with quotations from Islamic source texts—either hadiths or Quranic verses—that are then elaborated with a brief discussion and a list of issues for further consideration. Hadiths are sayings of the Prophet Muhammad that were passed down orally until gathered into written compilations in the ninth century. A tradition is referred to as *sahih* when it appears in more than one hadith and when its *isnad*—or list of individuals who orally transmitted it—is considered sound. The two most authoritative collections of hadith, those of Bukhari and Muslim, are often referred to as the two *Sahihs*, where *Sahih* is shortened from the title *al-Jami al-Sahih*.

“Muadh ibn Jabal related: ‘I was riding behind the Prophet—[may peace be upon him]—when he said to me: “O Muadh! Do you know what is due to Allah from His creatures, and what is due them?” I responded: “Allah and His Prophet know best.” He continued: “What is due to Allah from His creatures is to serve Him alone and never to associate any other being with Him. What is due them is not to punish any person who does not associate aught with Him.”’ The foregoing *hadith* is reported in the two *Sahihs*.”

Ibn Abd al-Wahhab quotes this tradition, generally accepted as authoritative, as part of a larger argument justifying his interpretation of monotheism in Islam. He uses passages such as this one to argue for two main tenets: that Muslims must refrain from showing devotion to anyone other than God and that those who fail to do this are eligible for punishment.

Muslims who rejected calls to conform to these beliefs could be attacked.

Ibn Abd al-Wahhab preached for several years in Uyayna, at the invitation of its chief, but was later turned out due to pressure from the regional tribal chief, supposedly after being approached by scholars who objected to Abd al-Wahhab's teachings. In 1744 he moved to Diriyya, whose tribal leader, Muhammad al-Saud, pledged to support him as long as he remained loyal to Saudi rule. By the time of Abd al-Wahhab's death in 1792, all of central Arabia was under Saudi control, an expansion aided significantly by policies condoning and even encouraging attacks on those who did not fall inside Abd al-Wahhab's limited definition of Islam.

Critics of the Wahhabi movement, which included Ibn Abd al-Wahhab's brother Sulayman, objected to its violent behavior and austere beliefs, which included razing tombs and enforcing strict punishments for moral transgressions. They argued that its founder was not sufficiently trained to issue such a thorough reinterpretation of Islamic sources. They particularly criticized the destruction of tombs and attacks on individuals who declared their belief in Islam but not the teachings of Wahhabism. However, Wahhabi ulama obtained a monopoly on religious interpretation in Najd by both driving ulama who opposed their ideas out of Najd and forbidding contact with all outside of the Wahhabi movement.

Abd al-Wahhab's approval of attacks against those outside of the Wahhabi movement enabled the Wahhabi-Saudi alliance to expand its control across Arabia, conquering Ottoman-controlled Hijaz in 1803 and 1804. Capturing the holy cities, Mecca and Medina, threatened Ottoman prestige and security, so the Ottoman sultan sent the newly modernized Egyptian army to intervene. Egyptian forces under Ibrahim Pasha, Muhammad Ali's son, landed in 1811 and by 1818 had destroyed the Saudi capital at Diriyya and sent the surviving Saudi and Wahhabi leaders to imprisonment in Cairo.

This seemingly complete destruction did not last long. Saudi and Wahhabi forces regrouped to form a second emirate, with Turki ibn Abdullah ruling much of central and eastern Arabia from 1824 to 1834. Turki's son Faysal succeeded him, yet was sent into exile after a second Egyptian

invasion installed relative Khalid Ibn Saud in 1937. The Egyptian army was forced to pull out in 1841. Turki escaped and ruled a smaller and less aggressive Saudi polity from 1843 to 1865. Succession disputes between two of his sons, Abdullah and Saud, threw the region into chaos. The Rashid family ended Abdullah's rule in 1887 and forced the family to flee to Kuwait in 1891.

This second emirate set important precedents with respect to restraining the attacks of Wahhabi supporters on foreign territories, an effort expanded by the founder of modern Saudi Arabia, Abd al-Aziz ibn Saud (r. 1902–1953). Starting in 1902, Ibn Saud campaigned to wrest back control of Arabia from the Rashidis and Ottoman-backed Hashimites, culminating with his declaration of the Kingdom of Saudi Arabia in 1932. He astutely balanced the pressure to spread Wahhabi religious ideas with political concerns, especially the need for good relations and cooperation with foreign entities.

The Baha'i Faith

The Baha'i Faith is a religion founded in Persia (present-day Iran) in the mid-nineteenth century by Mirza Hosayn Ali Nuri (1817–1892), who is known as Baha'ullah (Glory of God). It grew out of the Babi Faith, also founded in nineteenth-century Iran, by Mirza Ali Muhammad (ca. 1819–1850). The principal tenets of the Baha'i faith are the essential unity of all religions, the oneness of humanity, and equality between the genders. Much of Baha'i teaching is about social ethics, and its disciples devote themselves to the abolition of racial, class, political, and religious prejudices. The faith has no priesthood and does not observe ritual forms of prayer or worship.

Every Baha'i is obligated to pray daily; abstain from cigarettes, drugs, and alcohol; practice monogamy; obtain the consent of parents prior to marriage; and participate in the Nineteen-Day Fast between March 2 and March 21, during which they abstain from eating and drinking from sunrise to sunset. The Baha'is use a calendar in which the year is divided into 19 months of 19 days each. The year begins on the first day of spring, March 21, which is one of several holy days in the Baha'i calendar. The Baha'i faith unreservedly accepts the validity of other faiths. Baha'is believe that Abraham, Moses, Zoroaster, Buddha, Krishna, Jesus, and Muhammad are all equally authentic messengers of one God. But Baha'is believe that the messengers of God have come progressively: each revelation from God is more complete than the one preceding it, and each prepares the way for the next. In this view, Islam, as the most recent of the prior religions, constituted the immediate historical preparation for the Baha'i faith.

The Baha'i religion originally grew out of the Babi faith, or sect, which was founded in 1844 by Mirza Ali Muhammad in Persia, who assumed the title of the Bab (meaning "Gate"). He proclaimed a spiritual doctrine emphasizing the forthcoming appearance of a new prophet or messenger of God who would overturn old beliefs and usher in a new era. These beliefs originated in Shia Islam, whose followers believe in the return of the Twelfth Imam (successor of the Prophet Muhammad), who will guide and reward the faithful. The Bab's ideas were opposed by orthodox Muslims, and he was imprisoned and eventually executed in 1850. Subsequently his remains were smuggled out of Persia and brought to Palestine, where they were interred in present-day Haifa, Israel. One of the Bab's earliest disciples and strongest exponents was Mirza Hosayn Ali Nuri, who assumed the name of Baha'ullah. The Baha'is believe that Baha'ullah is the messenger announced by the Bab. They also believe that Baha'ullah is the Twelfth Imam expected by the Shia Muslims. Baha'ullah was arrested for his religious beliefs in 1852 and jailed in Tehran, where according to Baha'i belief he became aware that he was the prophet. He was released in 1853 and exiled to Baghdad, where his leadership revived the Babi community.

In 1863 shortly before being exiled to Constantinople, Baha'ullah declared to his fellow Babis that he was the messenger of God foretold by the Bab. An overwhelming majority of Babis acknowledged his claim and thenceforth became known as Baha'is. Before Baha'ullah died in 1892, he appointed his eldest son, Abd ol-Baha (1844–1921), to be the leader of the Baha'i community and the authorized interpreter of his teachings. Abd ol-Baha actively administered the movement's affairs and spread the faith to North America, Europe, and other continents. Presently, the faith has more than 150 national spiritual assemblies (national governing bodies) and about 20,000 local spiritual assemblies.

Islamic Modernism

The number of Muslim intellectuals espousing distinctly modern views of religion and politics was growing over the course of the nineteenth century. However, the development of the movement that has come to be known as Islamic Modernism is most often traced to the figure of Sayyid Jamal ad-Din al-Afghani (d. 1897), whose career as a Muslim reformist and anticolonial activist in many ways set a new paradigm for Muslim leadership. Jamal ad-Din's origins remain

Sayyid Jamal ad-Din "al-Afghani" was a tireless advocate of pan-Islamic reform as part of a cultural and political strategy to unite all Muslims against Western imperialist encroachment during the second half of the nineteenth century. (UCSB Davidson Library)

➤ MODERNISM ACROSS THE MUSLIM WORLD

Islamic Modernism is often associated with developments centered on Egypt in the late nineteenth and early twentieth centuries. However, it was in fact an intrinsically transnational movement even at its very inception. The first major journal espousing such ideas, *Al-Urwa al-Wuthqa*, was published by two Muslims from different parts of the Middle East working together in Paris in 1884. Its more influential successor, *al-Manar*, was published under Egyptian and Syrian editorship but came to influence Muslims worldwide through its circulation beyond the Middle East to various parts of Africa and Asia at the turn of the century and throughout the early decades of the twentieth century. During this same time other journals such as *Sirat-i Müstakim/Sebilürresad* (Ottoman Turkish), *Sura* (Tatar), *al-Imam* and *al-Munir* (Malay), and *Yuehua* (Chinese) professing similar reformist agendas began appearing all around the Muslim world in Arabic and other languages. While the historical moment of Islamic modernism had reached its zenith by the mid-twentieth century, the ideas first disseminated in *al-Manar* and other journals of its kind have had a considerable impact on later developments, including significant aspects of the global Islamic resurgence of the last decades of the twentieth century.

obscure, and it appears that he deliberately kept them thus. By midlife, however, he had emerged as a highly visible and globally mobile individual working for the advancement of Islamic political agendas in places such as London and Paris as well as Cairo and Istanbul. During Jamal ad-Din's lifetime, rapid progress in travel and communications technologies were allowing Muslims to receive and locally reinterpret ideas originating elsewhere. These exchanges of ideas and innovations fostered the creation of a wide variety of new conceptions of what it meant to be Muslim in the modern world.

Primary among Jamal ad-Din's causes were the unification of Muslims worldwide in a Pan-Islamic movement of resistance against European imperialism and demonstration of the compatibility of Islam with modern science. Jamal ad-Din's agenda of promoting rationalism in modern Islamic thought was more elaborately developed in the works of the Egyptian reformer Muhammad Abduh (d. 1905). Abduh called for a radical reappraisal of Islam's religious and intellectual heritages, and he became a proponent of a new wave of religious thought that championed a return to the foundational sources of the Quran and Sunna combined with a renewed emphasis on the place of human reason in their interpretation. Abduh expressed his mission in a fragmentary autobiography as understanding "religion as it was understood by the elders of the community before dissension appeared; to return, in the acquisition of religious knowledge, to its first sources, and to weigh them in the scales of human reason, which God has created in order to prevent excesses or adulteration in religion, so that God's wisdom may be fulfilled and the order of the human world preserved; and to prove that, seen in this light, religion must be accounted a friend to science."

His ideas became known throughout the Muslim world through the publication of influential periodicals under his editorship: *Urwa al-Wuthqa* (which he published with Jamal al-Din in exile at Paris in 1884) and later *al-Manar* on which he collaborated with his younger Syrian colleague, Rashid Rida (d. 1935).

Rida's reformism, however, was somewhat more conservative than that of Abduh and is often associated with the Salafi movement. During the late nineteenth century in Rida's native Syria, an active group of Salafi ulama attracted to the radical reformist thought of the fourteenth-century Hanbali scholar Ibn Taymiyya were already developing aspects of his medieval reformist ideas in new, more modern directions. Rida's own place in the further development of modern Salafism signaled a new turn in which Islamic modernism became more open to influences from a revived twentieth-century Wahhabism. Rida added to Abduh's modernist project a reinvigorated Salafi understanding of returning to the Quran and Sunna that became influential in the development of the

Egyptian Muslim Brotherhood and other Islamist movements all across the Muslim world in the twentieth century. In the lands of the former Ottoman Empire and beyond, Salafis set themselves up as strident critics of what they viewed as the weakening of Islam in the face of incursions from the modern West, which they perceived in the persons of secularizing Muslims as well as in the institutions of European colonial governments in the lands of Islam.

Jihads in the Western Sudan

The first half of the nineteenth century witnessed the outbreak of three religious wars, also known as jihads, in the western Sudan. The most famous and influential began in Hausaland in 1804 under the leadership of Usman dan Fodio. It was followed by jihads in Massina under Seku Ahmadu (Ahmad Lobbo) in 1818 and in the Futa Jallon area under al-Hajj Umar Tall in 1851. Caused by a combination of religious zeal and economic and political grievances, these movements had a lasting impact on the region.

Despite the spread of Islam in the region, in the eighteenth century whole areas still remained non-Muslim. Even in professed Muslim states, Islam was largely a religion of the towns, the ruling elite, and merchants. Although most of the ruling dynasties, especially in Hausaland, were Muslim, these dynasties were not strictly observant, and many unorthodox practices contrary to Islam such as illegal taxation, enslavement of Muslims, and unlawful seizure of property were common. Islamic and non-Islamic religious customs and practices existed side by side or were even blended. Revival of Islamic

brotherhoods such as Qadiriyya (which emphasized that salvation came through study and intellectual activity) in the second half of the eighteenth century also strengthened the belief in the coming of a Mahdi (savior) and aroused great expectations.

Nonreligious factors also contributed to the outbreak of the jihads. Politically, by the beginning of the nineteenth century no single large centralized state had emerged in the region. Many of the rulers of the western Sudanese states, especially the Hausa and Bambara kings, were petty tyrants widely despised for their favoritism and self-indulgence. Town-dwelling Fulani, many of whom were devout Muslims, despised their rulers for the luxury and sinfulness of court life as well as for their mistreatment of commoners. Merchants, peasants, and herders all complained over what they perceived as exorbitant taxation. One Fulani group in particular, the Torodbe or Toronkawa clan, was especially outspoken in its criticism of political and religious conditions in the region. Devout Muslims with a long tradition of religious scholarship but little access to political power, members of the clan resented their subordinate position and the fact that they took orders from their lukewarm Muslim and illiterate rulers. By the beginning of the nineteenth century, communities led by the Torodbe clan and individual scholars and preachers were found throughout the western Sudan preaching reform.

The most famous wandering scholar was a Fulani from Gobir, Usman dan Fodio, who was born in December 1754 into an old scholarly family of the Torodbe. After years of study, dan Fodio began to teach and preach in the Hausa states of Kebbi, Zamfara, and Gobir. He attacked non-Islamic religious practices, condemned corrupt and unjust governments and illegal taxes, advocated education for women, and insisted on complete acceptance of the spiritual and moral values of Islam. He soon attracted student disciples, many of whom returned to their homes to teach and preach in Hausaland and beyond.

In the late 1780s, Usman appears to have won the support of Sultan Bawa of Gobir, with whom he signed an agreement that granted Muslims freedom of religion and guaranteed respect for Islam. Taxation was decreased, and Muslims

➤ USMAN DAN FODIO'S CALL FOR HOLY WAR

In 1804 Usman dan Fodio called for jihad against the rulers of Hausaland. Such a war, he argued, was obligatory “by assent,” that is, the consensus of the Muslim community. The passage below is taken from a document attributed to this leader titled “Dispatch to the Folk of the Sudan and to Whom So Allah Wills amongst the Brethren.”

“Know then, my brethren:

That the commanding of righteousness is obligatory by assent. . . .

And that to make war upon the heathen king, who will not say ‘There is no God but Allah’ is obligatory by assent. and that to take the government from him is obligatory by assent. . . .

And that to make war on the king who is an apostate . . . and who has abandoned the religion of Islam for the religion of heathendom is obligatory by assent. . . .

And to make war against the king . . . who has not abandoned the religion of Islam as far as the

profession of it is concerned, but who mingles the observances of Islam with the observances of heathendom, like the kings of Hausaland for the most part—is (also) obligatory by assent, and that to take the government from him is obligatory by assent. . . .

And to make war on any backsliding Muslims who do not own allegiance to any of the Emirs of the faithful [lieutenants of Usman] is obligatory by assent. . . .

And that to enslave the freeborn amongst the Muslims is unlawful by assent, whether they reside in the territory of Islam, or in enemy territory.”

A. D. H. Bivar, “The Wathiqat Ahl Al-Sudan: A Manifesto of the Fulani Jihad,” *Journal of African History* 2(2) (1961): 239–240.

imprisoned for religious reasons were released. The agreement also allowed Muslim men to wear turbans and women to wear veils, both of which became hallmarks of Usman’s followers. Still dissatisfied, Usman in the mid-1790s began to raise the possibility of jihad, or holy war. In response, Bawa’s successor, Nafata, withdrew the privileges and outlawed new conversions to Islam. Nafata’s successor, Yunfa, also determined to check the growing power of dan Fodio, captured and imprisoned some of Usman’s followers in December 1803. When Usman liberated the captives at Degel and repeatedly refused to hand them over, Yunfa threatened to attack Degel itself. This led to the *bijra* (flight) of dan Fodio and his followers from Degel to Gudu on February 21, 1804. At Gudu, he raised the standard of revolt by attacking the nearby town of Gobir and then, having been proclaimed commander of the Believers, proclaimed a jihad against the rulers of the Hausa states. Various Fulani rose up in rebellion in the other states, and many Tuareg and Hausa peasants also joined the cause. Within a decade, all the principal Hausa states had been conquered. In the next two decades Nupe, parts

of the Oyo empire (Ilorin), and Borno (Katagum and Gombe) were added to the Fulani empire, with its new capital of Sokoto.

Usman’s success resulted in part from the weaknesses of the Hausa states, which had been divided by internecine wars for much of the eighteenth century. Oppressive rule, economic hardships, and social ills rallied Fulani and non-Fulani behind Usman. The zeal and determination with which he was able to infuse his followers by his preaching, coupled with the military ability of Abdullahi and Bello, his brother and son, respectively, were also important factors.

Other important jihads followed. Between 1818 and 1844, Seku Ahmadu (b. 1775), Usman’s disciple, unified a number of smaller Bambara, Arma, and Songhai kingdoms and principalities to establish the highly centralized Fulani theocratic state of Masina. In 1852 under al-Hajj Umar (1794–1863), a Tukulor, another jihad was directed not only against western Sudanese rulers but also against the French, who had begun their imperialist drive in the region of the Senegambia. Although he died in 1863 before he created an effective administrative machinery,

Umar created a Tukulor state that lasted until its overthrow by the French in 1893.

These jihads had far-reaching political, economic, and social consequences. They brought about fundamental political changes in which larger kingdoms replaced petty states. Usman's jihad led to the establishment of a single Fulani state in place of the many competing states in Hausaland. The state, known as the Sokoto Caliphate, was the largest political unit in nineteenth-century West Africa. Political centralization decreased the number of wars in the region, which in turn stimulated agricultural and handicraft industries, particularly in Hausaland. Trade increased, with Kano becoming the hub of commercial growth in Hausaland. All three jihads led to the Islamization of the region and in consequence a revival of Islamic scholarship and education.

The Mahdiyya Movement in Sudan

In Sudanese history, the Mahdiyya (from Mahdi, “guided one,” in Arabic) refers to a revolutionary movement that overthrew the Ottoman-Egyptian regime in the early 1880s and established a government in Sudan that lasted until 1898. The Ottoman province of Egypt, which had gained increasing autonomy under the rule of Muhammad Ali (1805–1848), had conquered Sudan in 1820–1822. Muhammad Ali and his successors sought the country's supposedly abundant mineral and human resources to finance Egyptian modernizing projects, help create a new army, and develop both agricultural and industrial enterprises.

After six decades of foreign rule, large sections of the Sudanese population were restive for various reasons. First, they disliked the government's growing reliance on European Christians

such as Samuel Baker, governor (1869–1873) of Equatoria (an Upper White Nile region that would henceforth become the most southern province of Sudan), and Charles George Gordon, governor (1874–1876) of Equatoria and governor-general (1877–1880) of Sudan. These British officers were appointed by the Egyptian khedive Ismail Pasha (1863–1879) to spread Ottoman-Egyptian control over the upper reaches of the White Nile and fight against the slave trade. Second, heavy taxation resulted in famine, depopulation, and migration, whereas the growth of cities such as Khartoum and El Obeid posed an economic challenge to the older urban centers of Sennar, Wad Medani, and Shendi. Third, many Sudanese—above all merchants from the Dan-aqla and Jaliyyin tribes who had moved to the province of Kordofan because of fiscal pressure and riverine farmers of the Nile Valley relying on slave labor—opposed governmental efforts to suppress the lucrative slave trade. Finally, Sufi leaders resented the presence of Azharite ulemas (al-Azhar was and remains the world's leading center of Sunni Islamic learning) in Sudan's judicial and educational institutions, which challenged their own authority. Adhering to Sufi orders such as the Sammaniyya, the Khatmiyya, the Ismailiyya, and the Majdhubiyya, the Sudanese population felt alienated by the more doctrinaire Islam preached by Egyptian ulemas.

Hence, when Muhammad Ahmad bin Abdallah (born on August 12, 1844, in the Dongola district and died on June 22, 1885, in Omdurman) publicly proclaimed himself the Mahdi on June 29, 1881, at Aba Island (White Nile), large numbers of Sudanese joined his cause and prepared to fight against the Ottoman-Egyptian government. According to Sunni doctrine, which largely prevails in Sudan, the Mahdi should appear at the end of time to restore true religion and spread social justice throughout the world. Muhammad Ahmad's reputation as a Sufi sheikh of the Sammaniyya order as well as widespread expectations of the Mahdi linked to the approaching Islamic year 1300 (1882–1883 CE) contributed to popularizing the Mahdiyya among the Sudanese. In less than four years the movement managed to take control of nearly the whole of Sudan, occupying the capital of Khartoum on January 25, 1885. In these same critical

► HOW DID MUHAMMAD AHMAD LEGITIMIZE HIS AUTHORITY?

Muhammad Ahmad claimed to be the successor of Prophet Muhammad on the basis of a prophetic vision. While Ahmad's reputation as a sheikh of the Sammaniyya order certainly helped him gain disciples, the central strategy he used to legitimize his authority was the modeling of his movement on the historical heritage of the Prophet and the first caliphs. Like the Prophet, Ahmad sought to establish a unified community and required his disciples to swear an oath of allegiance (*baya*). Naming them Ansar in reference to the Prophet's first followers in Medina, he migrated to Jabal Qadir (November 1881), reenacting the Prophet's flight from Mecca to Medina (*hijra*). Ahmad appointed three *khalifa* among his close supporters, who were to represent the successors of the first caliphs of Islam. His successor as ruler of the Mahdiyya, Abdullahi al-Taaishi, was thus associated with Abu Bakr, believed by Sunnis to be the first caliph. The Mahdi's actual numerous military victories against governmental troops were perceived as further evidence of his mission's validity.

—Iris Seri-Hersch

years, Ottoman Egypt was shaken by the Urabi protonationalist revolt (September 1881), subsequent British occupation (September 1882), and the loss of Sudan (January 1885).

The Mahdiyya's territorial expansion was accompanied by the establishment of various administrative, military, and judicial institutions. Several governors were selected by the Mahdi to manage the provinces of the emerging Mahdist state. The army was divided into three commands, a treasury was constituted, and a chief judge (*qadi al-Islam*) was appointed. After the fall of Khartoum (January 25, 1885), the Mahdist capital was founded at Omdurman, just across the White Nile. Muhammad Ahmad centralized all decision-making powers in his hands. He banned the existing Sufi orders, condemning them as divisive and useless once the encompassing rule of the Mahdiyya had been established. He also abolished the traditional Islamic schools of thought (*madhabib*), recognizing

three exclusive sources for Mahdist law: the Sunna, the Quran, and prophetic inspiration (*ilham*). Independent judgment (*ijtihad*) became his exclusive right. New laws included the prohibition of pilgrimages to tombs of saints; the banning of alcohol, tobacco, and music; and the confining of women to the private sphere.

The Mahdi died on June 22, 1885, only five months after the collapse of the Ottoman-Egyptian regime. His successor, Abdullahi al-Taaishi (1846–1899), completed the transformation of the Mahdiyya into a state structure. His 13-year-long rule (1885–1898) was characterized by mounting internal and external challenges. The Ashraf opposition (relatives and supporters of the Mahdi belonging mostly to Danaqla and Jaliyyin tribes), which did not recognize him as the legitimate successor of the Mahdi, organized two great rebellions against the regime (in 1885–1886 and 1891). Fearing for his personal and political survival, Abdullahi became increasingly autocratic. He forced fellow Taaishi nomads to emigrate from western Sudan and resettle in Omdurman so as to strengthen his power base. With regard to foreign affairs, he attempted to continue expanding the Mahdiyya eastward and northward. Border warfare brought Sudan into conflict with Ethiopia for a few years (1885–1889), until the Ethiopian emperor Yohannes IV was killed at the Battle of al-Qallabat (March 9–10, 1889). Although Mahdist jihad primarily targeted British-occupied Egypt, physical and political obstacles prevented any attack until the summer of 1889. Sudanese forces were then overwhelmed by Anglo-Egyptian troops at the Battle of Tushki (August 3, 1889), which definitively crushed Mahdist territorial ambitions toward Egypt. In the 1890s, European progression into the Nile Valley, the Red Sea, and central Africa significantly pressured Sudan. While the British fought the Mahdist forces from Egypt (mainly from Suakin), the Italians advanced westward from their Eritrean colony. In the south, Belgian expeditions sent from the Congo Free State threatened the Upper Nile and Bahr al-Ghazal Sudanese provinces. After two years of southward progression along the Nile, Anglo-Egyptian armies eventually overthrew the Mahdist state in the Battle of Karari (September 2, 1898). The Condominium Agreement (January 19, 1899) formally established joint

Anglo-Egyptian rule over Sudan until the country gained independence on January 1, 1956.

The Aligarh Movement

The Aligarh Movement was one of the responses of Indian Muslims to the failure of the Indian Rebellion of 1857 (in which Muslims had played a major role) and the demise of the Mughal empire in 1857 (thus bringing to a formal end centuries of Islamic rule in India). Many Muslims retreated into the folds of religious fundamentalism, while some felt the need to modernize and reform. The Aligarh Movement became the champion of the latter group.

The movement reflected the dreams and efforts of Sir Sayyid Ahmad Khan (1817–1898), who came from an aristocratic Muslim family that had served the Mughal court with dedication and distinction. Educated at home by tutors and learned family members, he joined the East India Company as a clerk in the judicial department in 1839 and later rose to the position of a judge. During the mutiny he remained loyal to the British and had little sympathy for the rebellion’s tactics or jihadi rhetoric. After the mutiny, he tried to convince the British and Muslims alike that they were not natural enemies and that past differences grew out of ignorance and erroneous stereotypes.

Khan’s message to the Muslims was provocative. He attributed the Indian Muslim community’s spiritual, educational, and economic stagnation to its parochialism and its

indifference and even hostility to science. He suggested that the meaning and application of the *shariat* (religious law) should be based on reason and attuned to modern times. He also held that future progress of Muslims in India depended on cooperation with the British and not confrontation.

Khan traveled widely to promote his modernist agenda through lectures, meetings, and conferences. He also spearheaded the formation of translation societies, literary associations, and scientific organizations to engage as many Muslims as possible. Khan started newspapers and journals both in Urdu and English (the *Mohammadan Social Reformer*, the *Aligarh Institute Gazette*, and others) that promoted and publicized his ideas of educational reform, the liberalization of Islam, and Muslim-British accord. He also contributed to the founding of schools that reflected his ideas. His learning, energy, and charisma inspired many supporters and some detractors as well.

Khan’s greatest achievement, and a symbol of everything he stood for, was the founding of the Mohammadan Anglo-Oriental College in 1875 in Aligarh, which offered a modern

➤ THE ANTI-ALIGARH SCHOOL—DAR AL-ULUM

If Aligarh reflected Islamic modernism and reform, the theological seminary Dar Al-ulum (The House of Learning) formed by some *ulema* (learned scholars of Islam) in Deoband in 1866 was the opposite in its orientations and interests. Unlike a typical madrasa (religious school), it followed modern pedagogical techniques; depended on private donations; published books, pamphlets, and legal opinions on many Islamic issues; and designed a comprehensive syllabus for rigorous and sophisticated Islamic learning. The school acquired fame and moral authority for the quality of its education, scholarship, and public service, and its message and practices were emulated by other Islamic institutions. Its reading of the Islamic texts and traditions, although scholarly and coherent, were very conservative and traditional and stood in sharp contrast to the liberal sentiments of Aligarh.

—*Ahrar Ahmad*

curriculum through Western pedagogical techniques. Modeled on Oxford and Cambridge, with instruction in English and at first led by an English headmaster, its purpose was to produce refined, progressive, and aristocratic Muslims. It depended on private donations and some financial support from the British government. This college became Aligarh University in 1920.

The college mostly catered to the Urdu-speaking Muslim elite from northern India. But for Muslims throughout India, it symbolized educational enlightenment, a rationalist orientation toward Islam, and religious tolerance (among Muslims and Christians and Hindus). However, and perhaps ironically, Khan and the Aligarh Movement may have contributed to the divisions between the Hindus and Muslims that had lasting consequences.

In 1885, mostly Hindu leaders formed the Indian National Congress, an organization that reflected nationalist sentiments and demanded democratic reforms. Concerned that supporting such an organization would anger the British and fearful that Muslims would suffer under Hindu majorities in any future democratic arrangement, Khan strongly opposed Muslim participation in the congress. The idea that Muslim interests were different from those of the Hindus led to the idea of Muslim separatism, encouraged the formation of exclusively Muslim organizations and political parties, and eventually led to the demand for an independent Muslim state. Consequently, while the Aligarh Movement was not political, its message played a role in the formation of Pakistan in 1947.

The Faraizi Movement

The Faraizi movement was a movement of religious reform with socioeconomic overtones that began in the 1830s and was centered in several districts of the province of Bengal in eastern India. It gradually faded in the 1860s with the deaths of its main leaders. It represents a rare example of religious extremism among South Asian Muslims.

The initiator of the movement was Haji Shariatullah (1781–1840) from the Faridpur district in Bengal. He came from a family of small farmers and attended religious schools. He went to Mecca for his pilgrimage when he was 18 years old, stayed there for the next 20 years, and studied under a master called Tahir Sambhal. Shariatullah fashioned a simple theology emphasizing *taubid* (the unity and singularity of God), *tauba* (being penitent and seeking forgiveness for past sins), and a notion of the *ummah* (the faithful) that stressed the egalitarian message of Islam and the brotherhood of all Muslims. Upon his return to Bengal, he was pained and disgusted at the many local (un-Islamic) customs and traditions that were part of Muslim practice. In response, he called on Muslims to abandon the rites and rituals that it had absorbed from Hinduism (for example, celebrations and ceremonies surrounding marriage, birth, and death) and to eradicate some Shia and Sufi influences, such as the worship of saints, the veneration of shrines, and the commemoration of the murder of the Prophet's grandsons. Shariatullah emphasized a rigorous adherence to the observances required of all Muslims (called the *Farz*, or "one's duty," hence the name Faraizis) through a strict devotion to the real teachings of the Quran and Hadith as embodied in the virtues and practices of original (i.e., early) Islam.

Shariatullah also embraced some populist themes. He denounced the exploitation of poor peasants by the *zamindars* (landowning classes), who imposed whatever taxes and exactions they wanted on the peasants, and commercial groups who forced them to cultivate cash crops such as jute, cotton, indigo, and opium and paid them poorly. Shariatullah challenged the cruelties and inequities inherent in the

► THE PERMANENT SETTLEMENT ACT OF 1793

The East India Company became the land revenue collectors of the province of Bengal in 1765. In 1793, Governor-General Lord Cornwallis decided to fix the annual revenue amounts payable to the company in perpetuity (hence the Permanent Settlement Act) and gave the Indian contractors responsible for making these payments proprietary rights over the land. The assumption was that these new landowners (*zamindars*) would develop their properties and that this would rationalize land revenue collections. Unfortunately, it created absentee landlords

and generated a system of subinfeudation (a multitiered hierarchy of subtenant farmers). This system increased the exploitation of the peasants through arbitrary taxes because the landlords charged their subtenant farmers amounts in excess of the fixed payments due to the company. In eastern Bengal many of the new landlords were Hindu, while most of the peasants were Muslims. Hence, both class and faith were sometimes interwoven in peasant uprisings such as the Faraizi movement.

—Ahrar Ahmad

system, which led to the victimization of peasants by usurious moneylenders.

Consequently, on the one hand, the movement mobilized the faithful by declaring the region as a *Dar al-Harb* (abode of war) in which the Muslims must be militantly engaged in protecting their faith and identity from hostile forces (the British and Hindus). On the other hand, it encouraged the Muslim peasants to resist the collection of taxes and *abwabs* (assessments) imposed by the *zamindars* as well as the exploitative demands and practices of the commercial and money-lending groups. Confrontations were inevitable, and sporadic skirmishes lasted through the 1840s. By then leadership had passed to Shariatullah's son Muhsinuddin Ahmed (popularly known as Dudu Mian), under whom the movement assumed a stronger opposition to the landowners. He trained groups of *lathiyals* (people who could fight with bamboo staves and clubs) so they could defend the community from the armed men (sometimes the local constabulary) serving the zamindars and traders. Some of his followers desecrated Hindu temples by killing cows and destroying images of Hindu deities. As the movement became more defiant and better organized, it faced more aggressive and determined retaliation from its opponents, both

through increasing physical force and also harassing lawsuits charging them with insubordination, violence, and nonpayment of taxes.

Dudu Mian was imprisoned by the British during the Sepoy Mutiny in 1857, released in 1861, and died a year later. The movement sputtered and gradually died down. While the actual impact of the Faraizi movement is difficult to establish, there is no doubt that its symbolic effect continued to linger in the folk narratives of the region and remains a significant event in the evolution of peasant activism in India.

■ Introduction: Native Religions in Africa, the Americas, and Oceania

Although the nineteenth century was a time of revival for Hinduism, intellectual ferment in Japanese and Chinese Confucianism, and geographical and numerical expansion for Islam, Judaism, and Christianity, it was also a time when many religions lost followers and coherence. Some religions disappeared altogether. Such was the experience of many of the numerous “traditional” religions practiced by the native peoples of Africa, North America, and Oceania. These religions, which varied from island to island in Oceania and tribe to tribe and village to village in Africa and North America, had lent meaning to the lives of millions of human beings over many centuries. Their creation myths offered profound truths about the qualities of their gods, the nature of the universe, and mankind’s place in it. Their sacred ceremonies provided a means to draw on supernatural and divine powers to prevent disasters and promote the success, stability, and prosperity of the community. Chiefs, elders, shamans, diviners, healers, ritual experts, and prophets provided religious guidance and inspiration for people for whom even the most mundane events of daily life were suffused with religious meaning. In the nineteenth century all of these beliefs and practices faced new and unprecedented challenges as a result of Western imperialism and the westward expansion of Canada and the United States.

These challenges came in many different forms. Forced relocation and forced changes in traditional ways of life (for example, the loss of hunting grounds and the relocation of Indians to reservations) rendered meaningless place- and activity-bound ceremonies and sacred rites. Contacts with Western medicine undermined confidence in ancient healing rituals; military defeats weakened faith in the powers of ceremonies, leaders, and divinities that once had brought success in warfare. Most directly, traditional religions were threatened by Christian missionaries who in large numbers worked among American Indians, Africans, and Pacific islanders in the 1800s. The lessons taught in their schools and the doctrines propounded in their sermons all

conveyed the same message: native peoples were backward and uncivilized and would remain so until they abandoned their false religious beliefs.

Demoralization and conversion to Christianity were two responses to the devastation faced by native peoples in the nineteenth century. A third was to draw on traditional religious beliefs and charismatic religious leadership to reverse their declining fortunes either by revitalizing religious practices through new ceremonies and practices or by inspiring armed resistance to the invaders of their lands. Religiously inspired resistance movements to colonialism were not limited to “traditional religions.” The Javanese prince Diponegoro, who led the armed struggle against the Dutch in the Dutch-Javanese War (1825–1830), was a religious visionary and devout Muslim whose followers believed that he was the Ratu Adil, the long-awaited savior king who had been part of Javanese beliefs for centuries. Later in the century Muhammad Ahmad bin Abdallah, a self-taught Muslim leader in Sudan, proclaimed himself to be the Mahdi—the successor of Muhammad and restorer of the faith—who founded the Madiyah (Mahdist regime), a state run according to strict Islamic principles (and his self-glorification) after leading a successful rebellion against Ottoman/Egyptian rule. Both movements ended badly. The Javanese suffered as many as 200,000 casualties in a losing cause, and Diponegoro was exiled to Sumatra. The Mahdist state came to an end in 1898 in the wake of the Battle of Omdurman, in which the army commanded by the Mahdi’s successor, Abdullah al-Taashi, sustained 27,700 killed, wounded, or captured, compared to British losses of 47 killed and 240 wounded.

The entries in this section describe five examples of the many native resistance movements inspired by prophets and spirit cults connected with traditional religions among native peoples. Two took place in Africa, two in North America, and one in New Zealand. They all show the continuing power of religion among peoples in desperate circumstances, but they also show the

inability of religious devotion alone to reverse their followers' fortunes and drive away the hated white man.

—*James H. Overfield*

Xhosa Cattle-Killing Episode

By the mid-nineteenth century, the Xhosa people in what is now present-day South Africa were experiencing serious social and economic crises. From 1779 to 1853, the Xhosa had been involved in eight wars (known as the Cape Frontier Wars or Kaffir Wars) with Dutch colonial (or Boer) and British settlers. By 1855, their cattle herds, which formed the basis of their economy, began to become infected with lung disease, which had slowly made its way into Xhosa territory from the European settlements at the Cape. Over the next several years, the disease killed 100,000 Xhosa cattle. In that atmosphere of defeatism and with the threat of famine, news began to spread among the Xhosa of the defeats suffered by Great Britain in the Crimean War. Those reports gave the beleaguered Xhosa a sense of hope and expectation that was perhaps exaggerated.

It was in that environment of ferment that Nongqause, the teenage niece of Mhlakaza, a respected prophet among the Xhosa, experienced her mystical vision. In April 1856, while Nongqause was attending to the corn fields near her uncle's cattle pen, she had been visited by several strange men, who identified themselves as her ancestors. They informed her that if the Xhosa destroyed all of their cattle and stopped planting new crops, the British would be expelled from Africa, and new, healthy cattle herds would replace those lost. The ritual sacrifice of the wealth of the Xhosa would thus usher in a new millennium. She reported that experience to her uncle Mhlakaza. He was skeptical initially but became convinced when the voices of the ancestors (one of whom was his own deceased brother) began speaking to him through his niece.

At the time, Mhlakaza was the most important religious figure among the Gcaleka Xhosa and an adviser to their chief, Sarili. In the early 1850s, he had left the Gcaleka community and traveled as a guide and interpreter for the eccentric English clergyman Nathaniel James

Merriman. The two had developed a close bond, and Merriman taught Mhlakaza (who briefly adopted the name Wilhelm Goliat) the basics of Christian theology. When those men eventually had a falling out, Mhlakaza returned to his village in 1853. However, his experience with the Christian missionary had inspired in him a zeal to become an influential preacher. It had also left him with a belief, influenced by both Christian and Xhosa concepts of salvation, that through the intervention of his ancestors, the tribulations of the Xhosa would soon end.

At the time of Nongqause's vision, Mhlakaza was under pressure from Chief Sarili to do something about the encroaching white colonists. After hearing his niece's story, he began killing his own cattle and instructing his followers to do the same. With the support of Chief Sarili, Mhlakaza's example inspired a wave of cattle killing and crop destruction throughout the Xhosa villages. Mhlakaza's command resonated with many Xhosa because it conformed to several of their strongly held spiritual beliefs. Within the Xhosa belief system, it was assumed that the travails of the community were the result of some malevolent force, which had to be countered by some supreme act of sacrifice. The Xhosa belief that the dead do not really die also promised that the sacrifice would not be in vain. Indeed, Nongqause was not the first Xhosa prophet to instruct her followers to slaughter their cattle as a way of relieving the woes of the people.

By the time Nongqause's followers had finished sacrificing their animals in July 1857, approximately 400,000 cattle had been slaughtered. The Gcaleka and their neighboring Xhosa communities were devastated with nearly 40,000 people starving to death, and an additional 35,000 fleeing the region. Nongqause herself escaped to the Cape out of fear of retribution. She was apprehended by the British, who imprisoned her ostensibly for her own protection. Mhlakaza perished in the turmoil unleashed by the mass killings in 1857. The death and departure of so many Xhosa from the region made their community even more vulnerable to colonial encroachment. The Xhosa were ultimately defeated in the ninth Cape Frontier War (1877–1878).

The Maji Maji Movement

In July 1905, rebellion broke out in the southeastern region of what was then the colony of German East Africa. Inspired by both internal peasant politics and the widespread rejection of German agricultural policies, the Maji Maji Rebellion grew into a social movement that encompassed much of the territory, posing one of the greatest threats to European colonial rule on the African continent. Spirit mediums, who were among the main organizers of the rebellion, initiated participants into the movement by distributing a medicine known as *maji* (Kiswahili for "water") that was believed to protect followers

from harm and turn enemy bullets into water. By 1907, the Germans repressed the movement in a scorched earth campaign that resulted in massive displacement, environmental catastrophe, and a devastating famine.

The motivations of participants in the Maji Maji Rebellion were rooted in the realities and politics of peasant life. In the decades prior to the German conquest, Tanzanian peasants practiced a system of agriculture designed for a complex ecological environment. Peasant households diversified their agricultural investments by cultivating their fields with a wide variety of crops, an approach that ensured that even in the worst of years at least one or two crops would survive. Chiefs organized communal labor parties to clear and burn brush in order to reduce the threat of pests such as wild pigs, locusts, and tsetse flies. In ideal circumstances, farmers turned over a portion of their surplus to a chief in exchange for protection and leadership. The chief held the surplus grain in storage and could redistribute it in times of shortage.

Colonial policy undermined the ability of East African societies to maintain this agricultural system and the social and political relationships it supported. The Germans, who sought to bolster their textile industry at home, forcibly conscripted labor for work on collective cotton plantations. The redirection of labor toward the cotton plantations meant that less work could

THE POLITICAL LEGACY OF MAJI MAJI

Immediately after the repression of the Maji Maji rebellion, many East Africans resented the movement's organizers for having led people into a disastrous losing battle. However, by the 1950s Tanganyikan nationalists, who were agitating for political independence, found inspiration in the memory of Maji Maji. Julius Nyerere, who later became Tanganyika's first president, addressed the following words to the United Nations in 1956:

"The people fought because they did not believe in the white man's right to govern and civilize the black. They rose in a great rebellion not through fear of a terrorist movement or a superstitious oath, but in response to a natural call, a call of the

spirit, reigning in the hearts of all men, and of all times, educated or uneducated, to rebel against foreign domination. It is important to bear this in mind . . . in order to understand the nature of a nationalist movement like mine. Its function is not to create the spirit of rebellion, but to articulate it and show it a new technique."

—Emily Callaci

Source

Julius K. Nyerere, Statement to the U.N. Forth Committee, December 20, 1956, in *Freedom and Unity* (Dar es Salaam: Oxford University Press, 1966), 40–41.

be devoted to the community task of clearing brush and ridding the land of pests. On the eve of Maji Maji, many farmers bitterly noted the return of pests that in previous decades had been kept at bay. Moreover, the imposition of taxes redirected grain surpluses to the colonial regime and away from community famine reserves.

Women were particularly burdened by German colonial policy, for as men were removed from the rural economy and conscripted for cotton cultivation, women were left to run the family farms on their own, performing the household labor of both men and women. Because of their grievances, women were often at the forefront of struggles associated with the Maji Maji rebellion.

In July 1905, Kinjikitile Ngwale was possessed by the spirit Hongo, a subordinate spirit of Bokero, who was venerated at shrines in the Matumbi Hills of present-day southeastern Tanzania. Kinjikitile built a hut from which he distributed a medicine called *maji*, which was believed to protect the movement's members and turn the enemy's bullets into water. Activists and intellectuals transported the *maji* medicine throughout the region, bringing many different groups—both states and stateless societies—into revolt. At times, acts of revolt targeted the German colonial state directly, while in other cases they attacked local chiefs and officials who worked with the Germans.

One of the remarkable aspects of the Maji Maji Rebellion was its geographic scope. The *maji* medicine and the message of Hongo started out as a means of organizing political action based on the shared cosmology of the Bokero cult. However, as the *maji* medicine traveled along long-distance networks of trade and migration, people who were not associated with Bokero joined the rebellion as well. The expansion of Maji Maji was due to the work of local intellectual leaders, who translated the *maji* ideology of rebellion into local idioms so that it could address a wide range of local grievances.

By October 1905 Gustav Adolf von Götzen, the German colonial governor in East Africa, deployed troops throughout German East Africa to put down the rebellion. Götzen's approach privileged the destruction of food reserves and infrastructure over direct military confrontation,

and in addition to executing thousands of leaders and participants, German forces burned and looted the villages and granaries of those who took part in the rebellion. This led to long-term economic and ecological devastation throughout the region that would later become the modern nation of Tanzania. Estimates for the number of deaths caused by the repression of the Maji Maji Rebellion range from 75,000 to 300,000.

The Religious Vision of Tenskwatawa, the Shawnee Prophet

Tenskwatawa, also known as the Shawnee Prophet, was born in western Ohio in 1775. His widowed mother left the family when the boy was still young, and he grew up in the household of a sister whose family regularly ignored him in favor of his brothers, particularly Tecumseh. Awkward and unskilled at hunting, considered clumsy and obnoxious by other Shawnees, Tenskwatawa eventually became an alcoholic.

By 1805, when Tenskwatawa began his new life as a prophet, 150 years of European contact had led to physical, cultural, and social displacement. Christian missionaries challenged traditional spiritual and religious leaders and beliefs. In response, nativist spiritual leaders such as the Neolin (Delaware tribe) and Handsome Lake (Seneca tribe) advocated moral and social reform, intertribal unity, abstinence from alcohol, and an end to land cessions. They called for a return to older spiritual ceremonies and traditions but also exhibited European influences.

THE BATTLE OF TIPPECANOE

By 1811 the village of Prophetstown on the Tippecanoe River in present-day Indiana had become the center of Tenskwatawa's and Tecumseh's efforts to forge a powerful confederation of Native American tribes dedicated to Tenskwatawa's nativist movement. In November 1811, with Tecumseh absent on a recruiting mission to the south, Governor William Henry Harrison, fearful of a new Indian menace, gathered approximately 1,000 troops on the outskirts of Prophetstown. Tenskwatawa assured his followers that the Master of Life would protect them from American weapons and ensure a victory for the Native Americans. Early on November 7, Native American forces launched their attack.

The Battle of Tippecanoe marked a turning point. After stiff resistance, the Native Americans briefly retreated to Prophetstown before abandoning the village. Entering the deserted village on November 8, Harrison's troops set fire to it after tearing up the burial ground and scattering the corpses. The discredited Tenskwatawa fled to Canada. Although he remained influential, Tecumseh would never see his dream of a unified Native American confederacy fulfilled.

—Kimberly Hogeland

Tenskwatawa's conversion experiences thus fit well into this pattern of nativist movements.

In the early spring of 1805 Tenskwatawa began preaching a new religion based on a near-death experience and a series of visions. In his visions a Master of Life presided over heaven, a paradise for virtuous Native Americans, as well as an eternal fire reserved for those who did not repent their sins. As in older Shawnee traditions, a Great Serpent symbolized evil, but Tenskwatawa added a political dimension, identifying the serpent with white settlers in the Ohio Valley region.

Tenskwatawa urged his followers to turn away from destructive behaviors such as intertribal violence and alcohol abuse and to focus on traditional ways. Native Americans should use bows and arrows instead of guns, reject imported animals and goods, and dress according to traditional styles and materials. Adherence to such doctrines would bring about the return of

Portrait of the Shawnee prophet Tenskwatawa, by George Catlin. (Smithsonian American Art Museum, Washington, DC/Art Resource, NY)

dead relatives and the game that had been disappearing from the forests.

The popularity of the Prophet's message caused concern among government officials. In 1806 Indiana governor William Henry Harrison challenged Tenskwatawa to produce a miracle, hoping to discredit him. Having learned of a summer eclipse from scientific parties in the area, Tenskwatawa called his followers together to announce that on June 16 the Master of Life would produce a black sun in affirmation of Tenskwatawa's power. The successful prediction only increased the Prophet's reputation.

The prominence of Tecumseh, the Prophet's brother, grew along with Tenskwatawa's. The western Great Lakes region proved particularly susceptible to Tecumseh's attempts to build an Indian confederacy. Although the region had few U.S. settlers, Native Americans saw proof of American encroachment to their south and east. Tensions between the brothers and American officials culminated in the Battle of Tippecanoe in November 1811. After his defeat, Tenskwatawa fled to Canada and died in obscurity. Tecumseh

continued as the leader in the confederacy and continued to fight against the Americans until his death in battle in 1813. Although Tenskwatawa never again played a dominant role in tribal affairs, his influence should not be underestimated. Tecumseh is generally credited as the driving force behind the native resistance movement in the early nineteenth century, but Tenskwatawa's religious teachings played a large role in drawing native people together.

Wovoka and the Ghost Dance Movement

By the end of the nineteenth century, war, disease, dispossession, and forced migration had caused catastrophic damage to Native American populations in the United States and strained traditional systems and practices. Periodic messianic movements held great appeal for tribal people trying to navigate these tumultuous times. Charismatic prophets taught that adherence to traditional practices and repudiation of European goods and ways would reverse the effects of recent upheavals.

Two such movements directly influenced the 1890 Ghost Dance. On the Columbia plateau, in the present-day state of Washington, the Wanapum religious leader Smoholla emphasized the relationship between people and the earth. He specifically preached against signing away or dividing up the earth. Smoholla's teachings spread and fueled the popularity of another movement, the 1870 Ghost Dance. Fearful of white encroachment, Wodziwob, a Northern

Paiute prophet in present-day Nevada, drew heavily on regional ceremonies and taught that through the traditional circle dance, adherents could bring about the return of ancestors and a renewal of the land. His movement spread to California and Oregon but lost support when his prophecies did not come true.

In 1890 the Ghost Dance movement was revived as a result of the teachings of another Northern Paiute man, Wovoka, who came from Nevada's Walker River reservation. Born around 1858 to one of Wodziwob's apostles, Wovoka (also called Jack Wilson, having spent much of his childhood on the nearby Wilson ranch) also spent time in Washington and Oregon, where he was exposed to Smoholla's teachings. On January 1, 1889, Wovoka fell ill during a solar eclipse and experienced his Great Revelation. During this episode, Wovoka claimed that he received instructions from God: if Indians would

WOUNDED KNEE

Forced onto reservations, denied access to their traditional activities, and provided insufficient rations, the Lakota proved receptive to the revitalization promised by the Ghost Dance. The movement's popularity provoked rampant rumors among the local non-Indian population, and by the late 1890s the government stationed half of the U.S. Army on the reservations. On December 15 Sitting Bull, a powerful and influential leader known for his role in the Battle of the Little Big Horn and his opposition to white encroachment, died in a shootout between his followers and reservation police forces at Standing Rock reservation, which only added to the tension.

On December 28 the Seventh Cavalry found a band of Lakota led by Big Foot. Greatly outnumbered and plagued by cold weather, illness, and a lack of supplies, Big Foot's people readily surrendered and were settled into rough camps along Wounded Knee Creek. For reasons that remain unclear, on the morning of December 29 soldiers opened fire on the Indian encampment, killing nearly 300 people. The event signaled the end of large-scale celebration of the Ghost Dance; for many people, it also signals the close of the Indian Wars.

—*Kimberly Hogeland*

abstain from fighting and alcohol, work cooperatively with the white man, and dance the traditional round dance, they would be granted material rewards and equality in the next life. In a time when economic and cultural stress predominated among native groups, the message of the Ghost Dance found a receptive audience and rapidly spread east from Nevada through the Cheyenne, Arapaho, Sioux, Kiowa, and Caddo tribes.

Naturally, each group that adopted the Ghost Dance adjusted it for its specific political and cultural situation. The most famous interpretation came to be the one advanced by the Lakota, a Native American group centered in North and South Dakota. After a Lakota delegation visited Nevada in 1890, the movement quickly became popular among a people who had recently been confined to some of the most desolate reservations in the nation in western South Dakota. At the height of the movement, 3,000 Lakota from the Pine Ridge and Rosebud reservations gathered to dance. They believed that by dancing and wearing special shirts—which were supposed to deflect bullets—they could induce visions and bring about a world renewal that would restore the life they had lost. The whites and the reservations would be gone, and in their place would be resurrected ancestors and buffalo. Ironically, this version of the Ghost Dance was much more in line with the 1870 religion preached by Wodziwob than with Wovoka's vision, which emphasized nonviolence and cooperation.

The scale of the movement alarmed the federal government, and efforts to suppress the Ghost Dance led to the massacre at Wounded Knee in 1890. While the Ghost Dance largely disappeared from public attention, it did survive in isolated pockets throughout the twentieth century.

Prophetic Leaders among the Maori

European missionaries first permanently settled in the northern part of New Zealand in 1814, but it was not until the 1830s that significant numbers of Maori began to identify with the Christian faith. However, the nature of their conversion was in many instances limited. Christianity did not so much replace existing beliefs as became blended with them, and the religion was remolded in uniquely Maori terms. Depopulation and land dispossession following British colonization provided fertile grounds for a number of prophetic leaders promising deliverance from the increasingly difficult circumstances that the Maori people found themselves in during the mid-nineteenth century.

The written word that followed the missionaries introduced Maori to a wider world. Many Maori strongly identified with the Old Testament and its story of loss and exile. Papahurihia, from the northernmost region of North Island, was a prophet who gained many followers from the early 1830 and was the first of many Maori spiritual leaders to identify Maori as Jews. Although he rejected the missionaries and their teachings, aspects of the Christian faith were readily incorporated into Papahurihia's beliefs. This mixture of Christian, Judaic, and Maori influences was followed by many later prophets.

By the 1850s most Maori were at least nominally Christian. Introduced diseases to which Maori had no immunity took a heavy toll on the population in many districts, prompting a number of localized faith healing movements. Meanwhile, plummeting Maori numbers and a significant increase in European immigration after formal British annexation of New Zealand in 1840, but especially from the 1850s, prompted a crisis in British-Maori relations by the end of the decade. The loss of land and increasing exclusion of the Maori from a share in administering the affairs of the country were resented by many

Maori leaders. Some Maori blamed the missionaries for failing to prevent these outcomes and began to assert a more independent outlook in religious and other matters.

Warfare between the government and Maori communities followed, first in Taranaki from 1860 and then spreading to Waikato by 1863 and other parts of the North Island until 1872. Sweeping confiscations of Maori land provoked further resistance and resulted in the emergence of a number of new prophetic leaders with strongly millennial messages of hope, peace, and prosperity ahead.

In the Taranaki district Te Ua Haumene's Pai Marire ("good and peaceful") faith emerged following an 1862 vision in which the archangel Gabriel was said to have spoken to Te Ua. Maori were once more identified with the Jews, and a return to their lands was promised for those who followed the faith. Pai Marire attracted significant support from Maori in those areas most affected by war and confiscation but was condemned by the government as fanatical after the murder of several Europeans and was consequently suppressed where possible. Te Ua himself died in 1866 some months after being taken into custody by European authorities and paraded around the country in an effort to break his influence.

On the east coast of the North Island the Ringatu ("upraised hand") religion of Te Kooti Arikirangi Te Turuki gained many followers. Te Kooti and more than 300 other men and their families had been imprisoned without trial on the faraway Chatham Islands for nearly two years while arrangements were made to confiscate their lands. They organized a successful escape back to the mainland in July 1868. Pursued by government troops, Te Kooti and his followers struck back in November of that year, attacking the settlement of Matawhero and killing more than 50 people. He later espoused peaceful means of gaining redress for the grievances of the Maori people and was formally pardoned by the government in 1883 but continued to be stigmatized as a dangerous fanatic by many Europeans long after his death in 1893.

In the rugged and remote Urewera district, which had provided sanctuary to Te Kooti while

➤ TE WHITI-O-RONGOMAI AND TOHU KAKAHI

The Maori settlement of Parihaka became an important center of peaceful opposition to land confiscations from the late 1860s and was home to two great prophetic leaders, Te Whiti-o-Rongomai and Tohu Kakahi. Both men led a long-running campaign of passive resistance, plowing confiscated fields and pulling out survey pegs. Te Whiti and Tohu attracted many Maori supporters, and as a result Parihaka came to be viewed as an embarrassment by the government.

On November 13, 1881, nearly 1,600 armed Constabulary invaded the settlement. Far from offering resistance, the inhabitants of Parihaka welcomed the troops. Parihaka was nevertheless destroyed, its inhabitants dispersed, and Te Whiti and Tohu imprisoned for a lengthy period without trial. Both prophets continued to lead peaceful campaigns following their release in 1883 and their return to Parihaka. They died within months of one another in 1907.

Te Whiti's pacifist ideals and steadfast pursuit of justice have sometimes been compared with figures such as Martin Luther King Jr. and Mahatma Gandhi. The white albatross feather that became the symbol of Te Whiti's movement today continues to be worn by many Maori in Taranaki.

—*Vincent O'Malley*

he was being pursued by government forces before 1872, Tuhoe prophet Rua Kenana was believed by some to be Te Kooti's successor. Rua's semiautonomous settlement at Maungapohatu was invaded by police forces in 1916, and the prophet was seized and arrested. Two Maori were killed during the raid, and the prophet was imprisoned with hard labor for resisting arrest, prompting an unprecedented protest at the harshness of his sentence from the jury that had convicted him.

Prophetic leaders continued to emerge during the early twentieth century including the prophetess Mere Rikiriki, whose teachings not only gave birth to the Maramatanga faith but also inspired her relative Tahupotiki Wiremu Ratana. The Ratana faith drew mass support from many poor and dispossessed Maori after 1918.

From the mid-1920s Ratana focused increasingly on political goals aimed at improving the plight of Maori. The religion he founded continues to attract many followers today.

■ Introduction: Judaism in the Age of Emancipation

More so than any of the major world religions, Judaism underwent profound changes between 1750 and 1914. After their expulsion from their Palestinian homeland by the Romans in the first century CE, Jews scattered across Asia, Africa, and Europe, where they maintained their identity as a people despite living in hostile environments and suffering frequent persecution. By the mid-1600s, however, the number of Jews in the world had been reduced to less than a million, equally divided between eastern Europe and the Ottoman empire. At that point the number of Jews gradually began to increase, reaching 2.5 million in 1800, roughly 7.5 million in 1880, and more than 13 million in 1914. Equally dramatic demographic changes took place as a result of Jewish migration. In 1914 Judaism still was centered in eastern Europe, with 5.5 million Jews in the Russian empire, slightly more than 2.5 million in Austria-Hungary, and 300,000 in Romania, but there now were 2.5 million Jews in the United States; 600,000 in Germany; 250,000 in England; 100,000 in France, Argentina, and the Netherlands; 85,000 in Palestine; 75,000 in Canada; 50,000 in South Africa; and 20,000 in Australia. Unlike the situation in the 1600s, when most Jews lived in small villages, by 1900 Judaism had become a religion of large towns and cities. No fewer than 1.35 million Jews lived in New York City, 350,000 in Chicago, 175,000 in Philadelphia, and 150,000 in London. Major urban centers for Judaism in Europe were Warsaw, with 350,000, followed by Budapest, Odessa, Vienna, and Lodz.

The increase in Jewish numbers worldwide resulted in part from the new freedoms and economic opportunities afforded to Europe's Jews. Beginning in the 1500s as the religious passions of the late medieval and Reformation eras slowly cooled, Jews who had fled western Europe slowly began to return; some who had converted to Christianity or become crypto-Jews (Jews who secretly adhered to the faith while publically adhering to Christianity) began to openly practice their faith. Jewish communities once more emerged in the Netherlands, England, and commercial cities such as Livorno, Hamburg, and Bordeaux. Small Jewish communities in Germany and Italy continued to live under many legal restrictions, but under the protection of princes and some Catholic ecclesiastics, they no longer feared mob violence or expulsion. A turning point in modern Jewish history came during the French Revolution, when in 1791 the National Assembly granted full citizenship to all French Jews, who at that point mainly lived in Bordeaux and Alsace-Lorraine. In the 1790s legal equality also was extended to the Jews of Germany and Italy after conquests by the French revolutionary armies.

Setbacks soon followed, however. In 1808 Napoleon issued what Jews came to call his "Infamous Decree," which among other things forbade Jews from settling in certain areas of France, regulated Jewish loans, and forced Jews to attain special permits to engage in trade. After Napoleon's defeat, Jewish emancipation decrees in most parts of Germany and Italy were

rescinded, and ghettos were reinstated in dozens of cities. Similar restrictions were enforced in Austria-Hungary. Despite lobbying from Jewish leaders and sympathetic liberals, complete Jewish equality was attained only later in the century. In England, Jews gained full equality when they were permitted to sit in Parliament in 1858; in France, Germany, Italy, Austria-Hungary, and Switzerland, full equality was attained in the 1860s and 1870s. Living in these new circumstances, western and central European Jews in the late nineteenth and early twentieth centuries made outstanding contributions to journalism, the arts, medicine, business, and politics.

Change came more slowly in Asia and eastern Europe. In the Ottoman empire, Jews benefited from the reforms of the midcentury Tanzimat era, which accorded Jewish and Christian minorities equal rights with Muslims. In addition, as a result of pressure from the European powers, Romania and other Balkan states granted full civil rights to Jews after they achieved independence from the Ottomans in the 1870s. In most respects, however, continuity, not radical change, characterized Jewish life in Ottoman and former Ottoman lands.

The Russian empire stood out as the one great exception to the pattern of gradual Jewish emancipation. Russian tsars had virtually no Jewish subjects until the late eighteenth century, when the three partitions of Poland added hundreds of thousands of Jews to the Russian empire. Barred from entering Russia itself, Jews from the 1790s to 1917 were restricted to living in the Pale of Jewish Settlement, a region mainly consisting of recently annexed Polish and Lithuanian territory. Tsar Nicholas I (r. 1825–1855) sought to Russify his Jewish subjects by subjecting them to conscription in the army, where they were often pressured to convert, and by forcing them to accept government-trained rabbis as liaisons between their communities and the state. Despite such restrictions and pressures, many Russian Jews held out hope for emancipation, especially after the ending of serfdom under the liberal tsar Alexander II (r. 1855–1881).

Such changes in the Jews' political and social status had inevitable consequences for Jewish thought and practice. In western and central Europe, the late eighteenth century and the

nineteenth century were characterized by efforts to gain legal and civic equality, increased acceptance into mainstream European life, and the abandonment of certain features of Jewish tradition and practices. The latter was expressed in movements such as the Haskalah, or Jewish Enlightenment, whose supporters (known as Maskilim) encouraged Jews to study secular subjects, embrace rationalism, learn European languages, enter fields such as agriculture and handicrafts, and adopt the aspirations and manners of the non-Jews among whom they lived. Such ideas inspired the beginnings of Reform Judaism, which advocated changes in Jewish religious observance such as using vernacular languages rather than Hebrew in the liturgy, allowing men and women to sit together during services, introducing music, and shifting the Sabbath from Friday to Sunday. Such practices were resisted by the supporters of Orthodox Judaism, who advocated the meticulous observance of Jewish laws and customs. In the United States at the turn of the twentieth century as new waves of Orthodox Jews from eastern Europe settled in cities with Reform populations made up of earlier emigrants from Germany, many leaders turned to the Conservative Jewish movement that had first emerged in Germany; they regarded it as a conciliatory movement that might unify Orthodox and Reform Jews. In eastern Europe and the Ottoman empire, Jewish life was largely unaffected by such divisions, although even in these regions reformism and Haskalah had their advocates.

No matter where they lived, Jews were affected by the dark clouds of anti-Semitism in the latter decades of the nineteenth century. The growth of nationalism, new racial theories, anxiety over the rapid pace of social and economic change, resentment over Jewish prominence in business and the arts, and the revival of ancient religious prejudices all fueled this movement. Anti-Semitism in western and central Europe gave rise to right-wing anti-Semitic political parties, the proliferation of anti-Jewish books, and episodes such as the Dreyfus Affair, when France was convulsed by controversy in the 1890s after a Jewish army officer, Alfred Dreyfus, was accused of and convicted of treason for selling military secrets to the Germans on the basis of forged documents. In Russia, anti-Semitism

found a deadlier expression. Between 1881 and 1884 a rash of anti-Jewish rioting, set off by the assassination of Tsar Alexander II and festering resentment over debts to Jewish moneylenders, resulted in thousands of deaths and the destruction of many hundreds of Jewish homes. Tacitly supported by local police, many of the tsar's officials, and perhaps Tsar Alexander III himself, the pogroms were followed by the promulgation of the May Laws, which restricted areas where Jews could settle, outlawed Jewish leasing or management of agricultural estates, and prohibited Jews from conducting business on Sunday and Christian holy days. In the 1890s Jews were barred from living in Moscow and St. Petersburg and entering the legal profession.

In the face of heightened anti-Semitism, Jews in western and central Europe fought back by suing their slanderers, responding to their false allegations, and publicizing positive Jewish contributions to their countries and communities. The Jews' predicament also provoked more extreme responses. In Russia it sparked an upsurge of emigration, with no fewer than 2.5 million Russian Jews emigrating between 1881 and 1914. Pogroms and anti-Semitism also gave rise to the Zionist movement, which sought to encourage Jewish migration from Europe to Palestine with the goal of establishing a new Jewish homeland. Originally centered in Russia as a response to the 1881 pogroms and the May Laws, Zionism gained a broader following after the Vienna-based journalist Theodor Herzl convened the first Zionist Congress in Basel in 1897 after he was shocked by the outpouring of anti-Semitism in France during the Dreyfus Affair. After World War II the Zionists reached their goal with the founding of the independent State of Israel but only after Europe's Jews experienced the unspeakable horrors of the Holocaust.

—James H. Overfield

Origins and Spread of Hasidism

The Hasidim, a Hebrew term meaning “pious ones,” belong to a special movement within Orthodox Judaism. At its height in the first half of the nineteenth century, the movement claimed the allegiance of millions of Jews in eastern and central Europe, perhaps a majority of the

East European Jews. Hasidism was founded in eighteenth-century Padolia, a region in the central and southwest portions of present-day Ukraine by Israel ben Eliezer (1698–1760), who also became known under the title Baal Shem Tov, or “Master of the Good Name.” Hasidism emerged at a time of growing tensions within the sizable community of Polish-Ukrainian Jewry in the face of large-scale massacres, sporadic anti-Jewish violence, and growing dissatisfaction among lower-class Jews with what they considered the strict rigidity and formalism of Rabbinic Judaism and its stress on the study of the Talmud.

After the death of the Baal Shem Tov, the single most important characteristic of the movement became the leadership role of the Zaddik (Righteous One), the charismatic leader. Each Hasidic sect had its Zaddik, who determined virtually every aspect of his followers' spiritual and personal lives. In many instances miracles and/or extraordinary intellectual capabilities were attributed to a particular Zaddik. After the Zaddik's passing, leadership was usually passed from father to son. In its infancy the movement met fierce opposition from such figures as Rabbi Elijah ben Solomon, the Gaon (Sage) of Vilna (1720–1797), who objected vehemently to the Hasidic practices of ecstatic prayer and visions, belief in miracles attributed to Hasidic masters, and their denigration of traditional Torah study. The animosity grew to such an extent that in 1772 the Jewish community of Vilna disbanded the congregation (*minyan*) formed by the Hasidim and issued a ban (*cherem*) of excommunication against them.

In the late eighteenth and early nineteenth centuries the schism between Hasidim and the *mitnagdim* (opponents of Hasidism) widened. Both sides frequently denounced each other even to governmental authorities and engaged in heated polemics. Some degree of reconciliation did take place in the nineteenth century in response to the Haskalah (Jewish Enlightenment), which vehemently opposed both Hasidim and mitnagdim in favor of a secularized Judaism. Between 1815 and 1848, the struggle between the *maskilim* (followers of the Jewish Enlightenment) and the Hasidim, especially in Galicia, reached a fever pitch. Previous clashes between the various Hasidic dynasties gave way to a

solidarity within the Hasidic camp in response to the spread of the Haskalah. Unity of purpose among the various Hasidic groups became a major tenet during this time.

The initial spread of Hasidism came to an end by the 1830s, at which point a majority of Jews in the Ukraine, Galicia, and central Poland as well as smaller followings in Hungary and Belorussia-Lithuania became adherents of one or another Hasidic Rebbe (Hasidic leader). In the wake of the Haskalah and the increasing secularization of Jewish life in Europe, the dynamics of Orthodoxy changed. Opposed to all manifestations of modernity and secularization of Judaism, the Hasidim went on the defensive. Hasidic leaders castigated the newly emergent political Zionist movements, Jewish socialist workers' organizations, and radical political parties. While the number of Hasidim remained constant at this juncture, the appeal of the movement to attract more followers diminished.

Hasidism had become a strong and viable movement in eastern Europe by the third generation of Hasidic leaders in Galicia, now part of the Austrian Empire, Hungary, the Ukraine, central Poland, and Russia. In addition to the initial practices of ecstatic prayer and focus on the Rebbe, various schools of Hasidic thought also emerged by the nineteenth century. Several Hasidic groups such as Chabad (Lubavitch) in Lithuania as well as Gur (Gora Kalwaria) and Kotsk in Poland now emphasized intellectual pursuits and the serious study of biblical and rabbinic texts and legal codes. In the 1860s, Rabbi Abraham Bornstein of Sochotchov (Poland) founded the first yeshiva (school) under Hasidic auspices. However, the success of Hasidism resulted in open tensions between the different, often competing, sects during this period.

With the outbreak of violent anti-Jewish pogroms and implacable poverty in eastern Europe, Hasidic Judaism came to western Europe and then to the United States during the large waves of Jewish immigration in the 1880s. At the end of the nineteenth century and into the twentieth century, Hasidism expanded its influence to the political realm, thereby determining the direction of several important Jewish organizations and political parties in Israel and America.

—Steve Garrin

THE AVNEI NEZER

Rabbi Abraham Bornstein of Sochotchov (Poland) was a nineteenth-century Hasidic leader who is known by the title of one of his commentaries on the Torah: the *Avnei Nezer* (The Stone of the Crown). In that work he discusses the unifying effect of Torah study:

"In our present exile, as in the Babylonian, the Jews are dispersed among the nations, whereas in Egypt they lived together in Goshen. The reason is: before we received the Torah there was no force strong enough to bind the Jewish people together as a special nation, and therefore the Almighty decreed that they should all dwell in one territory. Today, however, our study of the Torah serves as the rallying point to unite us in our dispersion."

—Steve Garrin

Reform Judaism in the Nineteenth Century

Judaism's Reform branch first appeared in nineteenth-century Germany in response to Jewish emancipation, which had effectively removed the existing legal impediments to Jewish participation in the political, social, and cultural life of Germany. In 1810 Israel Jacobson (1768–1828) conducted a Reform service in the town of Sessen in Westphalia. By 1818 a Reform "temple"

THE PITTSBURGH PLATFORM

The following is an excerpt from the 1885 statement of beliefs of American Reform Judaism:

“We recognize in the Mosaic legislation a system of training the Jewish people for its mission during its national life in Palestine, and today we accept as binding only its moral laws, and maintain only such ceremonies as elevate and sanctify our lives, but reject all such as are not adopted to the views and habits of modern civilization. . . . We hold that all such Mosaic and rabbinical laws as regulate diet, priestly purity, and dress originated in ages and under the influence of ideas entirely foreign to our present mental and spiritual state. . . . We recognize, in the modern era of universal culture of heart and intellect, the approaching of the realization of Israel’s great messianic hope for the establishment of the kingdom of truth, justice, and peace among all men.”

—Steve Garrin

was founded in Hamburg by the local headmaster of the Jewish school.

Initially, Reform Judaism sought to institute standards of decorum and ritual in the synagogue service and a corresponding liturgy that reflected the contemporary aesthetics of Protestant Church practice. To this end the founders of Reform Judaism introduced nondoctrinal changes to synagogue worship such as abbreviated prayers and the use of the vernacular in liturgy and pulpit sermons as well as choral and orchestral accompaniment to synagogue worship. These Reform leaders, all laymen, did not intend to break away from normative and traditional Jewish practice or create a separate sect within Judaism. But as a new generation of university-educated German Reform spiritual leaders emerged in the second half of the nineteenth century, a more significant departure from traditional Jewish practices and beliefs began. Motivated by the scientific and academic study of the Bible and committed to fully realizing the promise of social and political integration into German life, the second generation of Reform clergy held the position that Jewish practices must adapt to the times. They justified

their call for change by contending that throughout its history Judaism had evolved in order to accommodate the various and disparate geographic, political, and social contexts in which Jews found themselves.

In the early years of the nineteenth century there was no consensus among the Reform leaders concerning the scope of innovation. Even among themselves the leadership of the Reform movement varied in their degree of attachment to tradition. The outstanding personality at that time was Abraham Geiger (1810–1874), a native of Frankfurt, a graduate of the universities of Heidelberg and Bonn, a rabbi, and a distinguished contributor to Jewish scholarship. Geiger was radically opposed to Orthodoxy, which he regarded as outdated, irrelevant ritual incapable of satisfying the cosmopolitan and acculturated Jewish citizens of modern Europe. To be sure, he did wish to construct a new form of Judaism but only by using materials to be found in the historical and normative Judaism (*halacha*) of the past. Geiger concluded from his academic study that Judaism is a constantly evolving organism. Just as biblical Judaism was not identical to classical rabbinic Judaism, so too the modern age calls for further evolution consistent with the changed political, social, and economic circumstances of post-Enlightenment European Jewry.

His approach was far less radical than that of his Berlin colleague Samuel Holdheim (1806–1860). Holdheim did not believe in the evolutionary character of Judaism. For Holdheim, only revolutionary change and a dramatic break with the practices and beliefs of the past could salvage contemporary Judaism. He maintained that the end of the ancient Hebrew commonwealth invalidated all of Judaism’s ceremonial law; only monotheism and the moral components remained. To be sure, Holdheim represented an extreme voice even in the context of Reform, but he remained an adherent of the movement.

For virtually all the early Reformers, the messianic idea and its concomitant notion of a return to Zion were no longer viable. They considered the Bible alone as authoritative; the Talmud and rabbinic law were essentially cast aside. Instead, Reform Judaism introduced the concept of the universal “mission of Israel,” replacing the wish for a return to Zion and adherence to rabbinic

enactments. The Reformers believed that Jews were a religious community that could accomplish its historical mission only in the Diaspora. Judaism existed not solely to worship the Lord in accordance with rabbinic law but rather to spread the rational faith in one God and His moral law to the world at large.

In Europe the radical platform of Holdheim was accepted only in the Berlin *Reform-gemeinde*, which Holdheim served as rabbi, and by a short-lived fringe group in Hungary. The Reform Rabbinic Conferences of the 1840s and the synods of 1869 and 1871 were sparsely attended, and by the last quarter of the nineteenth century in Germany the Reform movement lost its appeal due to the growing success of neo-Orthodoxy and the emerging new Conservative wing of Judaism.

In America, however, Holdheim's revolutionary reform took root and provided the ideological framework for American Reform Judaism. To be sure, not all Reform leaders in the New World were inclined to adopt so extreme a position, but by the end of the nineteenth century Holdheim's philosophy defined the movement ideologically. It was set forth in the so-called Pittsburgh Platform of 1885, the doctrinal credo of nineteenth- and early-twentieth-century Reform Judaism in America.

Orthodox Judaism

Orthodox Judaism as it is known today is not the same Judaism that existed before European emancipation of Jews. In its own way, it is also revolutionary and, like Reform Judaism, first gathered strength as a reaction to the

Enlightenment. Later, it reacted against the Reform movement specifically.

From the beginning of the nineteenth century, the goal of most Jewish leaders and rabbis in Europe was to stop the defection of Jews from Judaism. With the opening of the Jewish ghettos and the emancipation of individual Jews in the evolving nation states of Europe, it was becoming possible, for the first time, for Jews to live outside the Jewish community. They could accomplish this either through conversion to Christianity or simply by living a secular life, something that was not possible before the eighteenth century. While the new Reform movement claimed that making Jewish life easier and more modern could halt the trend away from Judaism, traditionalists saw these kinds of reforms as an imitation of Christianity and a step toward total assimilation. They searched for another way.

One of the early leaders of the Orthodox movement was Rabbi Samson ben Rafael Hirsch (1808–1888), a German Jew born in Hamburg who later worked in Frankfurt. Hirsch's father, Rafael, was an active opponent of the new Reform synagogue in Hamburg, and Samson took a similar position. Although he was not against certain changes to the service—in fact, during his younger years, he had been a friend of Abraham Geiger, the founder of Reform Judaism—he strongly objected to any rejection of Jewish law and to any questioning of the principles of Jewish faith. It was not Judaism, insisted Hirsch, but Jews, that needed reform.

One of Rabbi Samson Hirsch's first books was called *Nineteen Letters on Judaism*. This work, written in the form of letters between two young Jews, laid out his ideas on Jewish education and contained many innovations. Although many Jewish communities, especially those in central and eastern Europe, concentrated only on study of the Talmud, Hirsch believed in the study of the Bible as well. He also encouraged young Jews to get a university education so they could function successfully in the secular world. But he was not ready to compromise on the study or the observance of Judaism.

"Torah with *derekh erez*" was Hirsch's watchword. *Derekh erez* means, literally "the way of the land"; and this quote, originally found in the *Sayings of the Fathers* (*Pirkei Avot* 2:2),

➤ CONSERVATIVE JUDAISM IN THE UNITED STATES

Conservative Judaism, conceived in Germany—as was Reform Judaism—was an attempt to find a middle way between the Reform and Orthodox movements. Originally called Historical Judaism, this philosophy stressed the progressive interpretation of Jewish law throughout the ages but insisted on retaining all of the law. This idea contrasted with the Reform view that certain laws were no longer relevant and could be ignored.

The principal founder of the historical school was Zacharias Frankel (1801–1875), who was born in Prague but served in German cities for most of his rabbinical career. He believed that reform was needed in Judaism, but he wanted only reforms that did not conflict with the spirit of Historical Judaism. He also argued for continued use of the Hebrew language in the prayer book, and for retaining a belief in the Messiah and a hope for a return to Zion. Although he failed to establish a strong movement in Germany, Frankel set the

standard for modern rabbinical training that was adopted by a group of American Jews in the late 1800s. Isaac Leeser (1806–1868), an American rabbi, educator, and writer, was its first proponent, but others soon joined him. Most of these men had been educated in Germany, and all were traditionalists who advocated some change. They organized a rabbinical school in 1887 to train American rabbis. That school came to be known as the Jewish Theological Seminary. The Seminary's philosophy of "tradition and change" was attractive to eastern European Jews who were coming to the United States in the late 1880s. These immigrants sought a traditional synagogue that also made allowances for modern life. They felt comfortable in the new Conservative congregations where men could read the prayers in the familiar Hebrew, but were able to sit together with their wives and children and hear sermons in English.

—Emily Taitz

the last book of the Mishnah, implied that a person should be educated in Torah (that is, Jewish law as it was written in the first five books of the Hebrew Bible) and also in secular studies. Jews could study at a university and be enlightened citizens and still maintain loyalty to the laws of Judaism. Hirsch and his followers refused to accept the Reformists' idea that biblical law was developed over time to meet the needs of society. God gave the Torah in one revelation, they believed, and therefore individuals were not free to choose which laws to follow.

Although other factions among the traditionalists disagreed with various aspects of Hirsch's philosophy, they did agree on two main points: the God-given nature of the Torah and the laws, and the authority of the rabbis who interpreted those laws. They rejected the new concept of a science of Judaism, explaining that observance of all the 613 commandments (statements and principles of law and ethics contained in the Torah or Five Books of Moses) must come before speculation, before the objective study of those commandments.

Eventually, Reform and Orthodox split and formed two separate branches of Judaism.

Encouraged by the Orthodox faction, the two groups agreed that if a Jew wanted to leave the congregation because of differences of religious principle, that Jew could do so without leaving Judaism. This ruling was passed in Hungary in 1868 and in Germany in 1876. From that time on, synagogues were labeled either Reform or Orthodox.

Orthodox Judaism was sometimes referred to as neo-Orthodoxy to emphasize its differences from the earlier mainstream traditionalists. It spread west from Germany into France and England and was brought into the United States by German immigrants. It also spread eastward, capturing the imaginations of many of the more enlightened traditionalists of eastern Europe. The Hasidim did not join forces with neo-Orthodoxy. They remain separate, maintaining their own organizations and leaders and their own schools.

Anti-Semitism

Anti-Semitism, which gained increasing numbers of adherents in Russia and the Western world in the nineteenth century, is a durable, but not a unitary phenomenon, with the persistence of hostility to Jews as remarkable as the variety of justifications given for it. Anti-Semitism also varies in terms of its consequences. In the early Middle Ages, for example, the Jews were often bitterly denounced. But the Jews' function as a living witness to Scriptural truth meant that they must be preserved, not exterminated. Hence many popes and princes tried to protect Jews from popular violence.

In the High and Later Middle Ages, however, Europe's Jews were demonized. From the 1150s onward, Christian belief in the blood libel, which alleged that Jews stole Christian children to drink their blood at Passover, became widespread. Jews were popularly associated with the Devil, heretics, and imaginary witches. This development has been ascribed to the expansion of the medieval state, which sought to classify society and define outsiders as objects of persecution. During the Reformation Era, these images were combined with classical and theological stereotypes to license the persecution of Jews, who easily provided scapegoats for the schisms within Christianity. Martin Luther (1483–1546) notoriously denounced the Jews as haters of Christ, proponents of a theology of works rather than faith, and unwilling to work in honest professions.

Luther's charge of idleness is a sign of the rise of economic anti-Semitism. In the Middle Ages, many financial dealings such as lending money at interest, frowned upon by the Church, were entrusted to Jews (though not exclusively: banks developed, especially in Italy), who thus became indispensable but unpopular. Having been forbidden to practice crafts or agriculture, Jews were blamed for concentrating on

unproductive work. Many Gentiles encountered Jews as peddlers, supplying goods to isolated communities, or as middlemen buying and selling farm produce. With the growth of an international capitalist economy, and eventually with multinational banks like that of the Rothschilds, which rose to prominence in the eighteenth and nineteenth centuries, Jews were associated with money and, hence, with calculation, greed, and excessive rationality.

Within theological anti-Semitism, the Jews' supposed rationality was explained also from their adherence to an essentially intellectual law that was subjected to analysis in the Talmud. Secularization in the Enlightenment period juxtaposed this image of the overly rational Jew with a contradictory image, based on Jewish religious practice, of the Jew as addicted to irrational superstition and therefore unfit to enter enlightened society. Thus, Voltaire (1694–1778) describes the Jews in his *Essai sur les Moeurs et l'Esprit des Nations* (1753) as “always superstitious, always greedy for others' property, always barbarous, servile in misfortune, and insolent in prosperity.” More sympathetic Enlightenment thinkers thought Jews could enter civilized society by wholly abandoning what had long become a fossil religion: thus, Immanuel Kant (1724–1804) in his *Der Streit der Fakultäten* (The Conflict of the Faculties) claimed that “The euthanasia of Judaism can only be achieved by means of pure, moral religion and the abandonment of all its old legal regulations.” Hence, once theological barriers had fallen, the complete surrender of Judaism might admit Jews to enlightened European society.

Another barrier, however, was already appearing in the nineteenth-century form of modern nationalism. A nation (*Volk*) was defined by its territory, its physical character, and, above all, its language, which was the source of its creativity and the expression of its collective soul. Johann Gottfried Herder (1744–1803), the ideological founder of modern nationalism, judged the Jews by this standard to be merely a parasite on settled nations. Although Jews benefited in the late eighteenth and nineteenth centuries from emancipatory legislation, they also encountered a backlash that denied that they could really become members of national communities.

If nationhood was defined by language, then the Jews, it was alleged, could never truly master modern European languages. Either a distinctively “Jewish” intonation was always detectable or else Jews, however perfectly and indeed brilliantly they might write, revealed their difference by the sheer brilliance of their writing and by the overly intellectual irony they introduced. These charges were especially leveled at German poet, journalist, and essayist Heinrich Heine (1797–1856) by conservatives irritated by his politically subversive journalism. Heine, born a Jew, converted to Christianity as a young man, but always considered himself and presented himself as a Jew.

Nationalist anti-Semitism was radicalized by the famous composer Richard Wagner (1813–1883) in his immensely influential essay “Das Judentum in der Musik” (“Judaism in Music,” 1850). Wagner insists that Jews can speak European languages only as foreigners. Their real language, Hebrew, survives only as a dead, liturgical language. Hence they lack the creativity that comes from a living language spoken by a national community. Their excessive rationality also debars them from song, the language of the emotions. Synagogue music is merely fossilized, like the Jewish religion. Jews can acquire European culture only superficially, by buying into it, thanks to their commercial success, which is bringing about the Judaization (*Verjudung*) of Europe.

These stereotypes required only the spurious authority of “racial science” for full-scale racial anti-Semitism to be born. Racial anti-Semitism is based on the discounted theory that Semitic peoples, which includes the Jews, are inherently different from and inferior to the so-called Aryan people who supposedly first populated Europe. Since being Jewish was now considered to be a matter of blood rather than religious belief, conversion to Christianity could not erase the Jews’ many negative characteristics: laziness, greed, selfishness, cunning, and lack of patriotism. The aristocratic French writer Arthur de Gobineau (1816–1882) is often viewed as the first proponent of race-based theories of history. His *Essay on the Inequality of the Human Races* (1853–1855) divided the world’s peoples into three races (black, white and yellow),

among whom whites were superior, although the other races had some positive qualities. He believed history taught that chaos and decline resulted when the races mixed. Gobineau’s theories were not blatantly anti-Jewish, unlike those expressed in *The Foundations of the Nineteenth Century* (1899) by Houston Stewart Chamberlain, an Englishman who married Wagner’s daughter. Chamberlain’s book evokes an apocalyptic picture of pure, emotionally profound races (like the Germans) beleaguered by swirling masses of mongrels and groups of shallow, hyper-rational Jews. An equally apocalyptic message was propagated in the fraudulent *Protocols of the Elders of Zion*, first published in Russia in 1905. It purports to be a Jewish plan for taking over the world.

Unfortunately, late-nineteenth-century anti-Semitism expressed itself in more than the written word. As some Europeans began to look on Jews as a scapegoat to explain their personal or national failures and others came to view Jews as objects of jealousy for their success in business and the professions, public attacks on the Jews increased. From the 1880s to the early 1900s many thousands of Jews died or were expelled from their homes as a result of mob attacks in Russian Poland. In 1894 the French Jewish military officer Alfred Dreyfus was falsely convicted of selling secrets to the Germans and was sent to Devil’s Island before being exonerated after a series of politically divisive court challenges. In 1897 the virulently anti-Semitic politician Karl Lueger (1844–1910) was elected mayor of Vienna and served until 1910. Between 1905 and 1913, young Adolf Hitler lived in Vienna, where he was deeply influenced by the racist views of the city’s mayor.

Motives of Jewish Migration

Much of the story of Jewish migration in Europe from the mid-eighteenth century to the outbreak of World War I was a result of deportation, forced migration, and flight from persecution and violence. Jewish migration in this time period was overwhelmingly a process of leaving Europe altogether, though some did relocate to other areas in Europe. Nearly 3 million Jews, mostly from eastern Europe and Russia, left the continent of Europe for other destinations. Indeed, most Jewish migration within Europe in the 150 years before World War I was a process of moving through Europe and on to other places.

Jews in most European states had been granted emancipation (full civil equality by law) by the late nineteenth century. Emancipation came in 1789 in France with the French Revolution, in 1871 in Germany, in 1867 in Austria-Hungary, and fully in Great Britain in 1890. However, emancipation did not come before World War I in the Russian empire (which included most of modern Poland) or Romania, where the large majority of European Jews lived. They were under the constant threat of deportation and violence. In 1791 almost all Jews living in the Russian empire were forced by the imperial government to live in a restricted area called the Pale of Settlement, located mostly in what had previously been Poland. By the nineteenth century, Jews within the Pale were forbidden to live in rural areas except for certain villages and were forced to live in crowded cities. A census taken in 1897 revealed that all but 200,000 of Russia's Jewish people lived in the Pale of Settlement. Eventually, about two-thirds of the 20,000 Jews who remained in Moscow were viciously expelled from the city. At the same time, violence against Jews in the Russian empire was on the rise. Pogroms (anti-Jewish riots), many of them state-sponsored or supported by the state, became more frequent against Russian Jews.

Millions of east European Jews saw emigration as the only solution to the increasingly

> VIOLENCE AND JEWISH MIGRATION

Violence is what led nearly 2.5 million Jewish people to leave Eastern Europe during the late nineteenth and early twentieth centuries. Most of this violence came in the form of pogroms, or anti-Jewish riots. In the Russian Empire, pogroms were usually government-instigated, supported, or allowed. These pogroms, numbering in the hundreds, made life increasingly unbearable for Russia's Jewish population.

Serious violence against Russia's Jews began to emerge following the assassination of the Russian emperor Alexander II in March 1881. More than a hundred pogroms occurred under the approval of the Russian minister of the interior. One of the worst outbursts of violence occurred in April of the following year in the city of Balta. More than 1,000 Jewish homes and business were destroyed, 40 Jews were killed, and more than 20 women reported being raped. These pogroms caused much criticism from Western Europe, and for a time the Russian government tried to stop subsequent pogroms. However, Russia's Jews would have to bear more in the form of a well-planned pogrom in 1903 in the town of Kishinev. The outbreak of murder, torture, rape, defiling of sacred objects, and property damage lasted for three days until the Russian government ordered it stopped. In the end, 45 Jews (men, women, children, and even babies) were killed, nearly 600 were wounded, and more than 1,500 homes and shops were ruined.

—Philip Flowers

intolerable situation in the Russian empire. This sentiment was best expressed by a prominent German rabbi, Zacharias Frankel, who said that "for the Russian Jews there is only one way out; to leave Russia and settle under a sky where the law recognizes human rights." For some, western Europe became the final destination of migrations. Tens of thousands of Jews settled in west European countries such as France, Germany, Holland, and Great Britain. Nevertheless, even as early as the 1880s European countries began to either stop or greatly restrict the immigration of Jews from eastern Europe.

Because of these restrictions, for most Jews western Europe was only a stepping stone for

immigration to other parts of the world. Most Jewish migrants would have to travel overland to reach seaports on the Black, Baltic, or North seas. Many would have to travel by land out of Russia into Austria-Hungary, Germany, or Holland before they could reach a seaport. Jewish communities of western Europe even started organizations to help Jews as they migrated across Europe trying to reach their final destination. Approximately 1 million Jewish migrants passed through Great Britain alone before World War I on their way to other destinations.

For over 80 percent of the Jews who migrated out of Europe during the nineteenth and early twentieth centuries, the United States was their final destination, and over 2 million Jews, mostly from eastern Europe, migrated through and out of Europe and on to North America. Over 100,000 Jews immigrated to South America, and about 65,000 went on to Palestine. Other destinations for Europe's Jews were Argentina and South Africa.

Zionism

Zionism holds that Jews constitute a people and a nation. As a political movement, it supports the creation of a homeland for the Jewish people. Zionism began in the late nineteenth century, arising out of the general movement of nationalism and increased anti-Semitism. It soon became a well-organized and well-funded settlement movement focused on Palestine, which many Jews believe was the ancient homeland granted them by God. Zionism eventually contributed directly to the formation of the State of Israel

and continued to influence the politics of Israeli Jews for the rest of the twentieth century.

The word “Zionism” derives from Mount Zion, the high ground in Jerusalem just south of the Temple Mount and the traditional burial place of King David. The term was first used in 1890 by Austrian Jew Nathan Birnbaum. Zionists found justification for their movement in the Hebrew Bible (and Christian Old Testament) account of God giving the land of Israel to the Israelites in perpetuity and from the long-standing belief of Diaspora Jews that they would one day return to the Holy Land. Zionism also grew out of the rise of nationalism in the nineteenth century, as various European nations developed national identities and political systems. Many Jews at that time had a secular view of their Judaism. They abandoned their religious practices but embraced the concept of Jews as a people and a nation that deserved a national homeland. Other ideas, such as socialism and rationalism, also influenced early Zionists. Zionism was fueled by the persecution of Jews in many places in Europe, most notably the Russian empire. Jews came to believe, with some justification, that only a Jewish state could protect them.

Although other locations were suggested, Palestine seemed to be the obvious choice for the establishment of a Jewish nation. It had biblical connotations, and many Jews believed that it was their historical homeland. In 1862 Moses Hess wrote *Rome and Jerusalem*, which urged Jews to settle in Palestine in an agrarian socialist state. Hess and other writers, such as Ber Borochov and Nahum Syrkin, believed that Jews had become weak and downtrodden as a result of their centuries of working as merchants and pawnbrokers and that they needed to redeem themselves with healthful outdoor labor and socialism. Zionism and socialism often went hand in hand in the late 1800s and early 1900s. Many Jews looked on the creation of a Jewish state as an opportunity for them to build an ideal society, a religious community founded on the principles of socialism. This belief coalesced in a movement known as Labor Zionism, which held that the creation of a Jewish state must necessarily be part of a class struggle in which Jews

would become agriculturists, living on collective socialist farms known as *kibbutzim*.

From the late 1870s through 1882 some Russian Jews went to Palestine, then a part of the Ottoman empire, there to establish small farms in a movement that became known as the First Aliya. Beginning in 1882, thousands of Russian Jews immigrated to Palestine, fleeing from pogroms and Tsar Alexander III's 1882 anti-Semitic May Laws. These settlers called themselves *Biluim*, after a verse from the book of Isaiah. Their goal was to establish a Jewish national homeland in the land they called Israel. These first settlers nearly starved during their attempt to support themselves on land without adequate freshwater, and many of them left. Baron Edmond de Rothschild provided the remaining settlers with money to establish a winery, which soon became successful. The settlers also used his money to found the town of Zichron Yaakov.

In 1894 the Dreyfus Affair in France, which triggered an explosion of anti-Semitism in that country, persuaded many European Jews that anti-Semitism was a growing problem, even in the supposedly enlightened Western Europe. Theodor Herzl, a Jewish-Austrian journalist who covered

the trial, became a staunch supporter of Zionism in the course of the Dreyfus Affair. In 1896 Herzl wrote *Der Judenstaat* (*The Jewish State*), in which he called for the Jews to create their own homeland either in Palestine or in Argentina.

In 1897 Herzl organized the First Zionist Congress in Switzerland. It created the Zionist Organization (ZO), the goal of which was to raise money and buy land in Palestine so that Jews could settle there. Herzl was the group's first president. The group spent the next 52 years purchasing land and creating governmental procedures for the new Israeli state. It was later renamed the World Zionist Organization (WZO).

All Jews were allowed to join the ZO. People from countries all over the world came to the group's congresses, which were held every two years between 1897 and 1946. Members assembled in delegations according to ideology instead of geographic origin. Some Zionists were ardent socialists or communists. Many were vehemently secular or even atheists. Others had more religious leanings.

The ZO organized the Jewish Colonial Trust to handle financial matters. The Jewish National Fund, created in 1901, took responsibility for

➤ THE DREYFUS AFFAIR

In 1894 Alfred Dreyfus (1859–1935), a French army officer and a Jew, was accused of passing military secrets to the Germans on the basis of circumstantial evidence and an analysis of Dreyfus's handwriting. Although Dreyfus maintained his innocence, he was convicted by a secret court-martial and exiled to the French penal colony on Devil's Island in French Guyana. Over the next two years key documents disappeared, and the new chief of army intelligence, Colonel Georges Picquart, presented evidence that the incriminating documents had been written by another officer, Ferdinand Walsin Esterhazy, a noted anti-Semite. Refusing to reopen the case, the army reassigned Picquart to a post in Tunisia and acquitted Esterhazy in a military court despite strong evidence against him.

The famous novelist Émile Zola (1840–1902) came to Dreyfus's defense in January 1898 with the

publication of an open letter titled *J'accuse* (I accuse), to the French president. Zola accused the army and the government of anti-Semitism and complicity in a judicial cover-up. The French political Right and the Church hierarchy defended the army, warning of a Jewish conspiracy to undermine France. When Dreyfus was granted a new trial (only to have his conviction upheld), mobs gathered outside the courtroom chanting anti-Jewish slogans. Dreyfus received a presidential pardon in 1900 but was restored to his military rank only in 1906. For European Jews, however, this was a severe blow to any hope they had to assimilate fully into European culture. Theodor Herzl, the father of modern political Zionism, was living in Paris as a correspondent for a Viennese newspaper during the Dreyfus Affair, an experience that helped undermine his faith in the Jews' future in Europe.

—James King

purchasing land. The Anglo-Palestine Bank, established in 1903, provided financial services for settlers. Gradually the group created an infrastructure for the Jewish homeland that made the process of settling in Palestine easier than it had been in the 1800s.

In the early years of the twentieth century, Zionists debated whether Palestine was the ideal location for the Jewish homeland. In 1903 the British government proposed a Jewish homeland in parts of present-day Kenya and Uganda. This plan was known as the British Uganda Programme. Herzl suggested this to the Sixth Zionist Congress as a temporary safe haven for Russian Jews, but the Russian Jews themselves disliked the idea, and the Seventh Zionist Congress abandoned the idea in 1905. The Jewish Territorialist Organization wanted to create a Jewish homeland wherever it could, but it disbanded in 1917. In the 1930s the Soviet Union created a Jewish Autonomous Republic in the Far Eastern Federal District, but few Jews wanted to move there. For the most part, Palestine remained the sole focus of the Zionist movement.

During the early 1900s, many small groups of settlers went to Palestine. A number arrived there following the 1905 Revolution in Russia. Leaders such as Joseph Baratz and other settlers pooled their money, added to it contributions from Jews all over the world, and founded kibbutzim on plots of land that they lived on and farmed collectively. By 1914 there were kibbutzim throughout Palestine. Residents shared all work and all profits and governed themselves democratically.

Jews under Ottoman Rule

For Ottoman subjects, religious affiliation was the primary form of identification and community. Jews were second-class citizens; however, their treatment as non-Muslims in the Islamic state was comparable to that of other non-Muslim minority groups. Generally, the relationship between Muslim and non-Muslim communities was characterized by a mutually tolerant contempt in which each community kept to itself. Not until the nineteenth century, with the decline of the Ottoman empire, did Muslim hostility against non-Muslim minorities become common.

From the days of the Prophet Muhammad, Islamic rulers are recorded as dealing peaceably with non-Muslim minorities within their territory. This precedent was set by Muhammad, who recognized the rights of the other monotheists, in this case the Jews of Medina, so long as they acknowledged Islamic sovereignty. As with other non-Muslim minorities in a Muslim state, Jewish men were expected to pay the *jizya* tax, a tax for those who were not permitted to perform military service. Theoretically, non-Muslims, *dhimmis*, were technically prohibited some of the privileges granted to Muslim subjects, but during the sixteenth through eighteenth centuries the Turks rarely enforced these prohibitions. In practice, however, only in times of increased Muslim resentment against dhimmis, usually periods of economic hardship, were the laws forbidding dhimmis from riding horses, owning slaves, or selling wine actually enforced. In such periods, Christians typically bore the brunt of any hostilities.

However, the lesser status of dhimmis, Jews among them, in the Ottoman empire was clearly apparent in some respects. Since dhimmis could not testify against Muslims in court, they needed a Muslim to testify on their behalf. For this reason, Jews rarely appear in Turkish court

documents. Where they do appear, their names are often spelled incorrectly by the Muslim scribes, and their religion is noted to antagonistically denote their lower status. Overall, however, Jews had more rights as minorities during the height of the Ottoman empire (during the sixteenth and seventeenth centuries) than they did in European Christendom.

At the height of the Ottoman empire at a time when the activity of the Inquisition in Spain was peaking, a large number of Sephardic Jews migrated to Ottoman territories. This proved beneficial both for the Turks and the Jews. The Jewish communities brought with them connections to social and commercial networks in Europe, knowledge of European languages, and recent European technological advances such as medicine and movable type. The Turks trusted these new immigrants because they, unlike their Christian counterparts, had no religious or political ties with the emerging European states. Often the Turks brought, and at times even compelled, Sephardic Jews into newly conquered Christian lands for strategic and political reasons, offering them diplomatic protection in exchange for this relocation. This ultimately benefited the larger Ottoman Jewish community by providing it with an edge over other subjects both financially and through higher status.

It is not surprising, then, that the Jewish population and the Ottoman empire experienced a decline at approximately the same time, during the nineteenth century. These declines were in part the result of the rise of the European nation-states. European commercial interests favored, protected, and enriched local Christians. This strained the Ottoman empire economically, while other European advancements would eventually strain it politically and militarily. The midcentury reforms of the *Tanzimat* era were intended to modernize the empire with new taxation rules, universal citizenship, and conscription. The economically depressed Muslim majority resented the taxes and the new equalities granted to non-Muslims, who could pay an additional tax to avoid service. Hostilities increased dramatically and now focused on Jews rather than Christians. Further fueling these hostilities was the importation

➤ MILLET

With the *tanzimat* reforms of the nineteenth century, the Ottomans permitted each *millet*, or religious minority under their protection, to select a local cleric with authority over the community's laws and internal concerns. In truth, the Ottomans were more concerned with collecting taxes from each millet than with the cleric who ruled it. Previously, the term "millet" had connotations of sovereignty and thus did not properly apply to the Jews, who were not sovereign anywhere. However, the new nineteenth-century millet concept not only changed the current Ottoman policy toward non-Muslim minority groups but also inspired revisionist histories within Jewish communities. As a result, narratives about community leaders who predated the millet reform were told to reflect a greater sense of civil authority than they ever actually held. Thus, the tradition arose that the Jewish millet began in 1453, when Mehmed the Conqueror recognized Rabbi Moses Capsali as leader over all of the Jews in the Ottoman empire. Historically, however, Capsali had no jurisdiction beyond his Constantinople community.

—Spencer Allen

of European anti-Jewish animosity, including blood-libels.

The rapid Jewish decline also had internal causes, however. Not only did Jewish immigration cease, but those who could afford to leave the empire did, leaving the poor and the uneducated behind. Without European medical innovations, Jewish physicians native to the empire were no better trained than their non-Jewish counterparts. Advantages were lost in other fields as well, among these the loss of knowledge of European languages as native-born children learned the local languages, which further decreased the strategic value of Jews to the empire.

—Spencer Allen

Judaism in the United States

From the time of their first arrival in 1654, Jews have consistently experienced more tolerance and freedom in North America than was enjoyed by their counterparts in any other part of the world. Religious freedom, however, was both a boon and a bane to American Jews. Tolerance came with pressure to assimilate and give up much of what distinguished them as Jews. Jews consciously adopted American culture and

style, yet they also sought ways to hold on to their Jewish identities. Threading the path between assimilation and Jewish identity, Jews in the United States continuously defined and redefined what it meant to be an American Jew.

Between 2,000 and 3,000 Jews maintained a toehold in the eastern colonies and then the newly independent states after 1776. They primarily lived in port cities—New York, Philadelphia, Savannah, Charleston, and Newport, Rhode Island—associated as many of their families were with the transatlantic commerce that bound the Americas to Europe and Africa. Many of these first Jewish Americans traced their roots to Portugal, so when they worshipped they followed Sephardic (Iberian) practice. This remained true even after the Ashkenazi (Jews from Germany, Poland, Austria, and eastern Europe) outstripped them in numbers at the beginning of the 1700s. The bitterness that divided the Ashkenazim and the Sephardim in Europe did not generally carry over to British North America. Still, by the early 1800s Ashkenazi Jews were founding their own congregations and building their own synagogues.

A wave of Jewish immigrants began arriving in the United States from across central Europe in the 1820s. These new arrivals shifted the basis of defining American Jewish identity from the ethnic accommodation between the Sephardim and the Ashkenazim to outright conflict between those who would modernize Jewish practice and those who sought to maintain older Jewish rituals and customs. Modernization included such things as rejecting dietary restrictions, ending the practice of requiring women to perform ritual purification at the end of their menstrual cycles, and doing away with the *mechitza*, the barrier that separated the sexes during religious services.

Influenced by ongoing pressure to assimilate, many American Jews were already prepared to accept modernization, including the growing embrace of Reform Judaism. But resistance to such change was strong and widespread. A well-known story featured Louis Spanier, the president of the Bethel synagogue in Albany, New York, in an altercation with Rabbi Isaac Mayer Wise in 1847. In a dispute over the speed with which Wise was liberalizing synagogue practice

► JEWISH MERCHANTS AND THE DEVELOPMENT OF THE AMERICAN WEST

Well into the twentieth century the major enterprises of the American West involved hide and agricultural production, trade, and the extractive industries (mining, logging, and oil production). Starting in 1849, Jewish merchants arrived in the American West from central Europe, where limits on their economic opportunities had forced them to learn to work with people from many different backgrounds and cultures. Their experience fitted them naturally to the role of cultural and economic go-between in the multicultural West. They began by building much-needed stores near the mines and logging camps or within ranching communities. Often the “Jew store” would be the only institution in a community and so would become its social and economic center. From these small beginnings Jews in the American West developed trade networks, chains of mercantile enterprises, and banks, supporting new American Jewish communities and contributing vital economic building blocks to the development of the American West.

—Warren Wood

and ritual, Spanier struck Wise and knocked off his cap. After Wise left and formed a separate congregation, his career as the great champion of American Reform Judaism really began.

Another wave of Jewish immigration began in the 1880s, when millions of eastern European Jews began to sweep across the Atlantic. They came, as previous waves of Jewish immigrants had come, seeking to escape poverty brought on by anti-Jewish social and legal proscription. Their religious orthodoxy and village sensibilities made them seem intractably foreign to both Christian and Jewish Americans. Their numbers quickly surpassed those of established and Americanized Jews, who feared—justifiably it turned out—that their growing presence would give rise to greater anti-Semitism in America. The forces of assimilation would eventually cause most of the new immigrants to temper their orthodoxy, but it would be decades before Jewish America could entirely integrate its eastern European cohort. Meanwhile, a

faltering economy and growing nationalistic fervor and anti-Semitism would cause Americans to shut the door on Jewish immigration in the 1920s, helping to set the stage for destruction of European Jewry after the rise of the Nazis in 1933.

■ Introduction: Christianity

The entries in this section focus mainly on Roman Catholicism and Protestantism, two branches of Christianity centered in Europe and America, and as such, the first Christian churches to face the unique challenges created by the industrialization, social change, scientific progress, and political revolutions of the modern era. Although the new age brought with it a diminished political role for both churches and increased skepticism and secularism, especially among intellectuals, Christianity retained the allegiance of most Americans and Europeans. In the United States, Christianity had a stronger following in 1900 than in 1800. The number of Roman Catholics and Protestants in the world grew dramatically between 1750 and 1900 as a result of the tripling of Europe's population and even more dramatic population increases in the Americas. Protestantism and Catholicism also were beneficiaries of Western imperialism in Africa, Asia, and Oceania. Under the protection of

largely sympathetic colonial governments, Protestant and Catholic missionaries made relatively few converts in the short run, but they planted the seeds for the growth of Christianity in Africa in the twentieth century and, as educators, introduced countless Asians, Africans, and Pacific islanders to Western thought and values.

Changes and challenges were not, however, limited to Protestant and Roman Catholic Christianity. Developments within the Orthodox churches of eastern Europe and Africa are outlined in the remainder of this introduction. In addition, information about Christian missionary efforts in Africa and Asia is provided in the section that follows this one, "Christian Missionary Endeavors in Africa and Asia."

In southeastern Europe, Eastern Orthodox Christians were little affected by industrialization or science, but their religious lives were changed dramatically by the new ideology of nationalism. Taking advantage of the declining

power of the Ottoman empire, under which they had lived for three to four centuries, Greece, Serbia, Bulgaria, and Romania all won their political independence from the Ottoman empire and their religious independence from the Ecumenical Patriarch, who along with members of the Greek community in Istanbul (the Phanariots) had overseen the religious affairs of the sultan's Christian Orthodox subjects. A key step was taken in 1833, when in newly independent Greece the Church declared itself "autocephalous" ("self-headed," or autonomous), to be governed by a Holy Synod of bishops appointed by the king. In time, Eastern Orthodoxy came to be divided into several national churches, each dependent on its own national government but still in communion with other Orthodox churches and acknowledging the nominal primacy of the Ecumenical Patriarch.

As it declined, the Ottoman empire lost many of its old tolerances despite government efforts to improve the legal standing of the sultan's Christian and Jewish subjects. In the midst of the bitterly fought Greek War of Independence (1821–1830), Greek attacks on mosques and Turkish civilians resulted in savage Ottoman reprisals, including the massacre of the Christian Greek population of Istanbul in 1821, when a thousand clergy, including the Ecumenical Patriarch, were killed. Later in the century when Armenian Christians living in Anatolia began to demand greater independence within the empire, they became victims of a series of massacres in the Caucasus and farther south during the 1890s, including the burning alive of several thousand Armenians in their cathedral in Urfa in 1895.

For the Orthodox Church in Russia, the nineteenth century produced no developments comparable to the traumatic events of the early modern era, which saw both the split between the "Old Believers" and the established Church and also the takeover of Church affairs by the imperial government during the reign of Peter the Great (r. 1682–1725). Devotion to the Orthodox Church remained high among villagers and city-dwellers alike; holy men who wandered the land while practicing extreme asceticism had wide followings. Cults of many kinds continued to attract small numbers of fervent followers. They

included the *skoptye*, who castrated themselves to kill their sexual urges; the *khylists*, who gave themselves over to sexual debauchery after becoming possessed by the Holy Spirit; the *dushtels* ("stranglers"), who killed the terminally ill; and the *dhukobors*, pacifists who denied the divinity of Christ and influenced the great Russian author Leo Tolstoy. Members of the clergy participated in the many nineteenth-century debates about Russia's future and its relationship with the West. Although most Church leaders were Slavophiles who opposed Western influence on Russia, by the 1880s many parish clergy were beginning to question tsarist autocracy and side with one of the several illegal political parties then taking shape. It was a St. Petersburg parish priest, Father Georgii Gapon, who in 1905 led the mass demonstration of unarmed workers whose demands for social and political reform sparked the Russian Revolution of 1905.

In Africa, the venerable Coptic Church experienced a substantial revival in the nineteenth century. By the late 1700s after many centuries of Ottoman and Mamluk rule, the once large community of Coptic Christians in Egypt had dwindled in size and vitality in the face of legal restrictions, high taxation, and occasional persecution. Not surprisingly, many Copts joined forces with the French when Napoleon invaded Egypt in 1798. They paid dearly for their support of the French when Egypt returned to Ottoman control in 1801, but they saw their fortunes rise after the Albanian Muslim adventurer Muhammad Ali seized power in 1805 and established an independent Egyptian state. Although a Muslim, Muhammad Ali was single-mindedly focused on building Egypt into a modern state, and he chose the most qualified men for his administration irrespective of their religion. As a result, many Coptic Christians were chosen for high administrative posts, and the Copts were able to develop their skills in business and other professions. After Muhammad Ali's death, the Copts' situation continued to improve. During the pontificate of Cyril IV (1854–1861), the Copts rebuilt churches, reopened a number of monasteries, and founded several schools, including the Coptic Patriarchal College, which taught mathematics, science, Arabic, French, Italian, and English. Paradoxically,

the “Coptic Enlightenment” ended once the British took control of Egypt in 1882. The British bent over backwards to please Egypt’s Muslim majority and tended to favor them over the Copts in most matters. As a result, the Copts were strong supporters of Egyptian independence from Britain.

Recovery also marks the history of the Ethiopian Eastern Orthodox Church, which like the Coptic Church, had fallen on hard times in the years around 1800. In this case it was the result of a series of ongoing theological disputes and the political disintegration of Ethiopia itself, which had resulted in the loss of its southern provinces to the pagan/Muslim Oromo people. Ethiopia was reunited, and Ethiopian Orthodoxy was preserved as a result of the actions of three Ethiopian rulers: Tewodrus II (r. 1855–1868), Yohannes IV (r. 1872–1889), and Menelik II (r. 1889–1913), all of whom were dedicated to the country’s ancient faith. Tewodrus II enlisted Protestant missionaries to help craft artillery pieces that he put to good use against the Oromo and domestic enemies before using one of them to commit suicide in 1868. Yohannes IV brought a semblance of doctrinal unity to the Church when he convened a Church council in 1878 to settle a number of theological issues and continued his predecessor’s efforts to consolidate his power and defend Ethiopian territory. This set the stage for the exploits of the modernizing Menelik II, whose armies crushed the invading Italians in 1896 at the Battle of Adowa. The event, celebrated across Africa, was a triumph of authentically African Christianity and was yet another example of the ability of Orthodox religions to maintain their fidelity to their ancient rites and doctrines despite hardships and conflict.

—James H. Overfield

The Enlightenment’s Critique of Religion

One of the most prominent features of the eighteenth-century Enlightenment was the hostility of many of its thinkers to organized religion. This opposition varied from fighting for religious tolerance to outright atheism. Hostility to religion also varied between different countries.

Generally, England saw the least hostility between the Enlightenment and the Church, and France saw the most. Opposition to religion tended to be stronger in those societies with a powerful institutional Church.

Belief in religious tolerance was a distinguishing mark of the Enlightenment, shared by nearly everyone connected to it. The killing of persons for following the wrong faith epitomized everything that Enlightenment thinkers detested about the power of organized religion. The era of religious wars in the sixteenth and seventeenth centuries had demonstrated the destructiveness of religious conflict. Although British and French wars of religion had ended by the eighteenth century, religious intolerance could still kill, as in the famous Calas case of 1761. Marc-Antoine Calas, from a French Protestant family, committed suicide. His father, Jean Calas, was charged with having murdered him for wanting to convert to Catholicism. Jean Calas was tried, tortured, convicted on flimsy evidence, and executed. Other members of the Calas family were banished. The case attracted the attention of Voltaire, who believed that Jean Calas had been falsely executed and championed his rehabilitation. Jean Calas was exonerated in 1765, and the family was reinstated. This was one of several cases of religious persecution that attracted the attention of Voltaire and other French thinkers at this time. Voltaire started using the slogan in his correspondence *écrasez l’infâme*, or crush the infamy, referring either to Christianity or to religion.

Opposition to religious intolerance grew into a broader anticlerical critique of the economic, cultural, and institutional power of Christian churches. Enlightenment thinkers did not invent anticlericalism, which had a long history in Europe, and anticlericalism was limited by the fact that many Enlightenment philosophers themselves were Catholic priests or Protestant ministers. However, many aspects of clerical power, such as censorship, the repression of sexuality, and hostility to the theater, were targets of criticism.

Enlightenment thinkers did not just criticize the actions of churches, though; they also criticized the philosophical basis of religion itself, particularly those religions they were most

DAVID HUME ON RELIGION AND POLITICS

The Scottish philosopher David Hume's *Dialogues on Natural Religion* contains some of the strongest antireligious arguments of the Enlightenment:

"Is there any maxim in politics more certain and infallible, than that both the number and authority of priests should be confined within very narrow limits; and that the civil magistrate ought, for ever, to keep his fasces and axes from such dangerous hands? But if the spirit of popular religion were so salutary to society, a contrary maxim ought to prevail. The greater number of priests, and their greater authority and riches, will always augment the religious spirit. And though the priests have the guidance of this spirit, why may we not expect a superior sanctity of life, and greater benevolence and moderation, from persons who are set apart for religion, who are continually inculcating it upon others, and who must themselves imbibe a greater share of it? Whence comes it then, that, in fact, the utmost a wise magistrate can propose with regard to popular religions, is, as far as possible, to make a saving game of it, and to prevent their pernicious consequences with regard to society?"

—William E. Burns

familiar with, Christianity and Judaism. The Bible was attacked as the superstitious work of ancient savages, far inferior to modern writings as well as the works of the pagan Greeks and Romans. As science developed the idea of a rationally ordered world, less and less credibility could be given to miracles. The Scottish philosopher David Hume argued that not only was there insufficient testimony for miracles to be believed, but it was always more likely that a person would lie or be mistaken than that a miracle, a violation of the laws of nature, would actually occur. This argument, unlike previous Protestant attacks on Catholic miracle accounts, was directed against the miracles of Jesus and

other biblical accounts as well as more modern ones. (Hume's argument was not pressed with such vehemence as to prevent him from being friends with leaders of the established Presbyterian Church of Scotland.)

The Enlightenment critique of religion was not restricted to negative attacks but also included positive alternatives. Deism was a popular alternative to Christianity, and attracted many of the French and English philosophes and, less publicly, several of America's founding fathers. Deism was the belief in a single God (Deists denied the Christian Trinity), all powerful and all good. Deists believed that the necessary truths about God could be discovered through reason rather than the scriptural revelations of the Jewish and Christian Bibles. Deistic religion would reach its height in the Cult of the Supreme Being established in the French Revolution. Theism was embraced by a small minority among Enlightenment thinkers, the most prominent being Baron d'Holbach. Many philosophers found the argument from design, the claim that the universe itself could not have come into existence by chance, to be convincing proof of the existence of a God even if the philosopher's God bore little resemblance to the God of Christianity. Atheism was forbidden in European countries, and so it had to be expressed in anonymous or pseudonymous tracts. Atheism was closely allied with philosophical materialism, the belief that the physical world is all that there is. Materialists denied the existence of a soul as well as of God.

Much of the Enlightenment critique of Christianity was elitist, not intended to influence behavior beyond the social elite. Some Enlightenment philosophers endorsed religion as a way to regulate the behavior of the lower classes or women. They idealized those purportedly non-religious civilizations such as China or ancient Greece and Rome whose governing elites did not share in the superstition of the people.

Methodism

Methodism refers to a religious movement arising in England in the mid-eighteenth century as a reaction against the formality of the established Church of England and the intimidating doctrines of Calvinist denominations. The egalitarian doctrines of Methodism taught that salvation was available to all who sought it systematically through prayer, Bible study, and virtuous behavior. Initiated by John Wesley and Charles Wesley, Methodism spread rapidly among factory workers and managers in the emerging industrial economy and spread to many parts of the world as a result of English emigration to the United States, Canada, Australia, New Zealand, and South Africa, as well

as English missionary efforts in colonial Asia and Africa.

Brothers John Wesley (1703–1791) and Charles Wesley (1707–1788) first began to formulate the theological principles of Methodism while in residence at Oxford University, undergoing personal conversion experiences and participating in informal worship with comrades. After ordination as ministers in the Church of England, they left Oxford in 1735 to embark on remarkable careers of itinerant preaching, authorship, and hymn composition.

Wesleyan theology focused on a system of methodical spiritual cultivation that they believed would lead to conversion and salvation if followed devoutly. Methodism diverged from the Church of England's structures, dispensing with formal church membership, rituals, liturgy, and maintenance of clerical and social hierarchies in favor of personal conversion, self-discipline, and active participation in Bible study, prayer, and worship. Although some critics called their approach puritanical, the Methodists differed significantly from seventeenth-century Puritans in

➤ JOHN WESLEY—THOUGHTS UPON SLAVERY, 1774

Methodists in England and the United States became leaders in many areas of social justice, including prison reform and the abolition of the slave trade. Abolitionists drew on the writings and sermons of John Wesley, who in 1774 wrote a widely read pamphlet, *Thoughts upon Slavery*. In the following passage he addresses the captains of the slave ships.

“Are you a *man*? Then you should have an [*sic*] *human* heart. But have you indeed? What is your heart made of? Is there no such principle as compassion there? Do you never *feel* another's pain? Have you no sympathy? No sense of human woe? No pity for the miserable? When you saw the flowing eyes, the heaving breasts, the bleeding sides and tortured limbs of your fellow-creatures, was [*sic*] you a stone, or a brute? Did you look upon them with the eyes of a tiger? When you squeezed the agonizing creatures down in the ship, or when you threw their poor mangled remains into the sea,

had you no relenting? Did not one tear drop from your eye, one sigh escape from your breast? Do you feel no relenting *now*? If you do not, you must go on, till the measure of your iniquities is full. Then will the great GOD deal with *You*, as you have dealt with *them*, and require all their blood at your hands. And at that day it shall be more tolerable for Sodom and Gomorrah than for *you*! But if your heart does relent, though in a small degree, know it is a call from the GOD of love. . . . Today resolve, GOD being your helper, to escape for your life. Regard not money! All that a man hath will he give for his life? Whatever you lose, lose not your soul: nothing can countervail that loss. Immediately quit the horrid trade: At all events, be an honest man.”

—James H. Overfield

John Wesley, *Thoughts upon Slavery* (London: R. Hawes, 1774), 25. (Italics as in the original text.)

their rejection of the notion of election. Spiritual conversion, they believed, was not restricted to an elect; rather, grace would be dispensed to any individuals who devoted themselves to prayer and the pursuit of holiness through their thoughts and behavior.

The Methodists' belief that salvation was not limited to the elect predestined by God was conducive to social egalitarianism. The Wesleys and their fellow travelers actively evangelized among people neglected by the established church: workers in the new industries of the Industrial Revolution, including factory hands and coal miners. Early Methodist worship often included lay preaching and prayer leading, sometimes by people who would not be admitted to Church of England ministry, including women, slaves, and people with limited formal education. Methodist evangelists avoided complex theological wrangling. Although John Wesley taught that the Bible was the sole reliable source of guidance for Christians, Methodist preachers seldom engaged in analysis of obscure passages, relying instead on simple parables, clear directives, exhortations to avoid sin, and congregational hymn singing to draw great numbers to the faith. Methodists were urged to avoid intoxicants, swearing, and levity; they were to wear simple and modest clothing and not indulge in extravagance or wastefulness. As the movement evolved into several denominations, the Methodist chapels drew congregants from impoverished or struggling communities who felt unwelcome at exclusive Anglican churches or intimidating cathedrals. The lack of ceremony and emphasis on moral discipline led some observers, including Charlotte Brontë and Charles Dickens, to depict Methodists as dour and humorless. Methodism has splintered into many different communities; more than forty denominations worldwide identify themselves as Methodist, and many others have some historical relationship to the Wesleyan movements.

The Religion of Reason in Revolutionary France

Along with the Reign of Terror, the introduction of a so-called Religion of Reason was one of the most controversial and important aspects of Year II (1793–1794) of the French Revolution. In the space of a few months, the revolutionaries, led by Jacques-René Hébert (1757–1794) and Pierre-Gaspard Chaumette (1763–1794), tried to uproot France's historical adherence to Catholicism and to promulgate an alternative to Christianity. As part of the general state-sponsored de-Christianization campaign, which included the rationalization and secularization of a society where religion occupied a central place in daily life, this cult of reason involved an attempt by the state to suppress Christianity and replace it with a new revolutionary culture. Cult supporters sought to eradicate all the institutions, practices, and beliefs of the ancien régime—which they characterized as a society based on fanaticism, superstition, injustice, inequality, and privilege—and to replace them with a new system based on reason, liberty, equality, and fraternity. The origins of this rational religion stemmed from the Enlightenment's critique of religion and the Church and its characteristic attachment to reason as well as from the schism caused by the Civil Constitution of the Clergy (1791).

At the urging of Chaumette, in November 1793 the Paris Commune ordered churches of all denominations to be destroyed or to be closed and converted into arms repositories, schools, granaries, or municipal buildings. After being thus purified of their Christian associations, some were turned into Temples of Reason, where, according to its proponents, the formation of loyal citizens would take place. The most notable example of this is Notre Dame

cathedral, which served as a food warehouse and had many of its treasures stolen or destroyed. It was also converted into a Temple of Reason and later hosted the Festival of Reason on November 10, 1793.

Through a series of festivals designed to entertain and to reeducate the citizenry through the inculcation of republican and patriotic values, the revolutionaries created their own sacred spaces by drawing upon revolutionary ideology. Saints were replaced by revolutionary martyrs such as Jean-Paul Marat (1743–1793) and Louis-Michel Lepeletier de Saint-Fargeau (1760–1793). Other religious imagery was replaced by revolutionary symbols, including the tricolor flag, Liberty trees, and the red Phrygian cap, a symbol of freedom and the search for liberty. Church bells and other valuables were melted down for the revolutionary cause, while crosses, statues of saints, and confessionals were burnt at bonfires.

With this quasi-religious adherence to reason came the introduction of the new revolutionary calendar. Although adopted on October 5, 1793, by the National Convention, this new dating system retroactively established September 22, 1792 (1 Vendémiaire Year I), as its starting point to commemorate the proclamation of the French Republic and to inaugurate the new Republican Era. The Gregorian calendar was discarded and replaced with one that emphasized reason, nature, and agriculture; rationally divided the newly renamed 12 months into three ten-day units (*décades*); replaced Sunday with the Tenth Day (*décadi*); and eliminated saints' names and Christian feasts. The republican calendar survived until January 1, 1806, when it was abandoned by Napoleon. A similar process also involved the renaming of people, streets, and geographical locations so that all Christian references were replaced with the names of heroes of antiquity and the revolution.

Maximilien Robespierre (1758–1794) believed that these excesses destabilized the republic and would lead to unwarranted opposition. He responded by introducing an official cult of the Supreme Being, that drew on elements of Jean-Jacques Rousseau's (1712–1778) theistic civil religion. Robespierre hoped that

The Festival of the Supreme Being at the Champ-de-Mars, July 8, 1794, by Pierre-Antoine Demachy. The Cult of the Supreme Being was part of the de-Christianization campaign sponsored by Robespierre and the Jacobins. The intent was to make it the state religion of France, but the experiment was abandoned following the fall of the Jacobins in 1794. (Gianni Dagli Orti/Corbis)

➤ THE CULT OF REASON

The Culte de la Raison (Cult of Reason) was epitomized in the Festival of Reason held in the cathedral of Notre Dame on November 10, 1793. Although the cult had many local variations, it was a civic, naturalistic religion centered on the worship of liberty and reason. It featured women impersonating goddesses of Reason and was devoid of any Christian association. It was viewed by the devout as atheistic, Jacobin revelries. The cult also focused on defending the nation, the Revolution, and popular sovereignty. It emphasized the importance of civic rights and duties and the need to obliterate the memory of the past. Reason was depicted as the destroyer of fanaticism and superstition.

—Joan Gonzalez

this new moderate cult would help restore political and religious stability. The Cult of Reason was thus officially ended, and Hébert and Chaumette were subsequently guillotined in the spring of 1794. Temples of Reason were gradually replaced by Temples of the Supreme Being, and the Festival of the Supreme Being was

held on June 8, 1794. The establishment of this new religion partly contributed to Robespierre's downfall and the end of the Terror.

De-Christianization was spread by the sans-culottes, representatives on mission, citizen armies, and members of clubs and patriotic societies, yet it had little success because the average French person was not interested. This was especially true of women, who by keeping religious rituals alive became the leading opponents of de-Christianization and the Cult of Reason. While unsuccessful and disastrous in the short term, this episode permanently altered the relationship between church and state and greatly affected religious life and practice in France for the next two centuries.

The Established Churches in Nineteenth-Century Europe

Also called state churches, established churches are officially recognized and subsidized by the government of a nation. After the French Revolution, the established Catholic churches in France and Spain reorganized to adjust to the decline of their social and political influence. In England and Germany, evangelical revivals challenged the spiritual monopoly of the established Protestant churches. And the Orthodox churches of Russia and Greece gained autonomy from the traditional leader of Orthodoxy, the patriarch of Constantinople.

In France, the prerevolutionary Gallican Church was wealthy, powerful, and closely allied with the monarchy. During the French Revolution the Civil Constitution of the Clergy (1790) required clerics to take oaths of loyalty to the state, abolished monastic orders, and provided

for the popular election of bishops. The Concordat of 1801 signed between Napoleon and Pope Pius VII (r. 1800–1823) governed postrevolutionary relations between France and the Church. Although the Concordat acknowledged Catholicism as the religion of the French people, it did not recognize Catholicism as the official religion of France. After the Bourbon Restoration of 1814, church-state relations continued to be governed by the Concordat. For the remainder of the century France pursued a policy of *laïcité*, or complete separation of church and state. During the Third Republic, the principle of *laïcité* was fully realized with a 1905 law that precluded the French state from recognizing or subsidizing any religion.

The early-nineteenth-century Spanish Catholic Church was associated with the absolutism of Ferdinand VII (r. 1813–1833). Upon assuming the throne, Ferdinand set aside the Constitution of 1812, which set limits on the monarch's power, and revived the Inquisition with the backing of the Church. After suffering serious political and financial losses in the Peninsular War of 1815, Spanish monasteries fell into disrepair, and the Spanish Church was too poor to maintain its traditional social responsibilities. The ineffectiveness of the Church and its association with absolutist monarchy provoked anticlericalism and further weakened the social authority of the Church.

Evangelical revivals challenged the established Anglican Church in England. English revivals promoted puritan behavior, missionary work, and Bible reading. These revivals were typically led by nonconformist congregations, including Baptists, Methodists, Presbyterians, Quakers, and Unitarians. Referred to as low churchmen, nonconformists were denied civic rights enjoyed by orthodox Anglicans. The orthodox high-church Anglicans sought to preserve the status and privileges of the Anglican Church as a national institution amid calls for emancipation of the nonconformists and the disestablishment of the Church. Campaigns for emancipation led to a repeal of the Test and Corporation Acts in 1828 and the passage of the Catholic Relief Act in 1829, allowing nonconformists and Catholics to hold public office. At the same time, the Oxford Movement

was initiated by John Keble (1792–1866), Edward B. Pusey (1800–1882), and Richard Hurrell Froude (1803–1836) to reintroduce Catholic traditions into the Anglican Mass. The movement was academic and clerical, finding little resonance among the laity. But it did lead to the establishment of Anglican religious orders and a renewal of the liturgy. Several supporters of the movement, notably John Henry Newman (1801–1890), eventually left the Church of England and converted to Catholicism.

The Lutheran Church was established in the German states and Scandinavian countries. In Prussia, King Friedrich Wilhelm III (r. 1797–1840) combined the Lutheran and Reformed churches into a single Evangelical Christian Church in 1817, which produced dissent among both Lutheran and Reformed congregations. Similar unions were effected in the Rhineland-Palatinate (1818), Baden (1821), Hesse (1822), and Württemberg (1827). Churches in the German states witnessed revivals that lasted into the 1840s. Inspired by the Lutheran spiritual movement known as Pietism, these revivals advocated individual piety, spiritual inwardness, and righteous living in reaction to the Enlightenment rationalization of religion and an ossified orthodox Lutheranism. Pietism and the nineteenth-century German revivals influenced the theologian Friedrich Schleiermacher (1768–1834), who posited religion as a feeling of absolute dependence and emphasized the personal experience of religion over its objective elements, such as ritual and morality. Schleiermacher's liberal theology engendered a cultural Protestantism whose proponents sought to accommodate Protestant Christianity to nineteenth-century German bourgeois culture.

The nineteenth-century Orthodox Churches were nationally administered but maintained a common profession of faith. Since the reign of Peter the Great (r. 1682–1725) the Russian Orthodox Church had been administered by a Holy Synod, whose procurator was a layman appointed by the tsar. Eastern Orthodox subjects of the Ottoman empire were under the pastoral care of the patriarchate of Constantinople. As Greece won its independence, the Greek Orthodox Church severed itself from the authority of the patriarch and adopted a Holy Synod. As their

POPULAR PIETY IN NINETEENTH-CENTURY EUROPE

Church attendance declined in European cities during the nineteenth century, especially among the urban working class. Despite this decline, European Christians expressed their devotion by joining extraecclesiastical lay organizations, confraternities, student Christian associations, and missionary societies. Institutions of Christian sociability such as the YMCA (1844), the YWCA (1894), and the Salvation Army (1878) appeared in nineteenth-century English cities and combined evangelism, social work, sport, prayer, and Bible study. Missionary societies such as the English Baptist Missionary Society (1792) and the British and Foreign Bible Society (1804) ministered to the working class at home and to non-Christians in the European colonies. Over the course of the century women were also increasingly accepted as missionaries. This coincided with the increasingly prominent role that women were taking in their parishes and congregations. This rise in female piety corresponded with the growth of Marian devotion and Rosary societies among nineteenth-century Catholics. Marian devotion was facilitated by the Catholic Church's dogmatization in 1854 of the Immaculate Conception of Mary. Pilgrimages to the sites of Marian apparitions in Lourdes (1858) and Marpingen (1876) testify to the level of popular Marian devotion. Declining church attendance during the nineteenth century did not necessarily imply a secularization of European religion. Instead, it may underscore the new and diverse extraecclesiastical means by which Europeans could manifest their spirituality.

Catholic Cults of Miracles in France, Italy, and Spain

The nineteenth-century cult of miracles was part of a revival of popular Catholicism that took root after the French Revolution and the Napoleonic wars. Long in decline, the cult of miracles provided an outlet for Catholics to articulate a range of local, regional, and transnational concerns on their own terms. Varying in size, pilgrimages to sacred shrines and the veneration of relics and saints were a dramatic and public expression of the faith that helped focus discontent with trends of secular rationalism. Frequently a threat to secular and ecclesiastical authority, popular devotion brought about new forms of cooperation and oversight between clerics and laypersons and helped transform the Church from one based on territorial sovereignty to one based on popular support.

Though connected to important changes in both the Church and society throughout Europe, the cult of miracles was centered mainly in Italy, Spain, and France, where revolutionary upheaval, anticlericalism, and the shifting political fortunes of the Church were particularly acute. In Italy, the cult of St. Philomena, said to be a young Greek princess martyred in the fourth century, was revived when the discovery of the catacombs under Rome in 1802 supposedly led to the discovery of her bones and an alleged vessel containing her blood. In Spain, Marian

devotion helped provide an important antidote to those who saw anticlericalism as an instrument of modernization. But it was at Lourdes in France that the cult of miracles made its most dramatic reappearance. In 1858, Bernadette Soubirous went out with her sister and friend to collect wood. Falling behind her companions, Bernadette stopped to rest in a grotto near the Gave de Pau River. There she claimed to see the radiant figure of a young girl who, over the course of 18 such appearances, declared herself to be the Immaculate One conceived without sin and told Bernadette to build a chapel on the site of a hidden underground spring.

Part of a wave of similar apparitions that swept across Europe involving young girls in rural areas who claimed to be conduits for warnings about the poor moral state of society, Lourdes became an international pilgrimage site for millions who believed that its waters have healing powers. It has also become a focal point of attack for those who criticize the Church for promoting superstition. Lourdes nevertheless also represents an enduring symbol of Catholicism's complex adaptation to the modern world. As an icon of suffering, Mary is an especially powerful symbol among the poor and oppressed, whose devotion was encouraged by no less a figure than Pope Pius IX (r. 1846–1878). By dogmatizing Mary's Immaculate Conception on December 8, 1854, he legitimized the cult of miracles and promoted a renewed commitment to religious life

➤ CATHÉRINE LABOURÉ AND THE “MIRACULOUS MEDAL”

In 1830, the Parisian nun Cathérine Labouré claimed to have been visited by the Virgin Mary after eating a small piece of cloth that belonged to Saint Vincent, the founder of her order, the Daughters of Charity. The event struck a deep chord in French society and inspired an outpouring of Marian devotion. It was the first Marian apparition in almost 300 years and inaugurated the modern era of Marian apparitions. That Mary was also said to have announced her own birth “free from sin” in these apparitions gave a powerful impetus to the movement to dogmatize her

immaculate conception in 1854. In 1832, commemorative medals depicting the event were struck and were credited with saving people from cholera and with inspiring conversions. On the medal Mary is surrounded by the words “O, Mary, conceived without sin, pray for us who have recourse to thee.” On the reverse side below the large “M,” supported by a cross with a bar at its base, are shown the Sacred Heart of Jesus crowned with thorns, and the Immaculate Heart of Mary pierced with a sword.

—Richard Schaefer

that manifested itself in an explosion in religious orders across Europe. The centrality of Mary and the fact that the overwhelming number of the new religious devotees were women were part of a feminization of religion that involved a decided preference for female iconography and increased female participation in religious life in the nineteenth century.

Catholic Responses to Modernity—Pius IX, the *Syllabus of Errors* and the Vatican Council of 1870

As the modern principles of liberalism, nationalism, and democracy threatened to undermine the social and political influence of the Roman Catholic Church, the papacy responded by consolidating its ecclesiastical power with the creation of new dogmas and the condemnation of false doctrines. Hallmarks of this campaign included the elevation of the doctrine of the Immaculate Conception of Mary to dogma in December 1854 and the promulgation of the *Syllabus of Errors* in 1864. Pius IX (r. 1846–1878) completed this program by decreeing the dogma of papal infallibility at the Vatican Council of 1869–1870.

Pius IX began his pontificate by introducing liberal reforms to the Papal States. Although

OLD CATHOLICS

Founded in Munich in 1871 and led by the German theologian and historian Johann Joseph Ignaz von Döllinger (1799–1890), Old Catholics professed adherence to Catholicism but asserted independence from papal authority, seeking to maintain the historic traditions of the early Church in the face of modern innovations such as the dogmas of the Immaculate Conception and papal infallibility. Old Catholics elected bishops by vote of priests and the congregation, held services in German, and allowed clerics to marry.

—Stan Landry

sympathetic toward reform and Italian nationalism, he alienated republicans and liberals by refusing to concede to further political demands, such as granting a constitution to the Papal States. A republican-inspired revolution reached Rome in November 1848, and Pius fled the city. He returned in April 1850, restored by French forces.

As a result of his personal experience of the revolutions of 1848, Pius judged liberalism and its principles—freedom of speech, freedom of religion, separation of church and state, and representative government—as grievous threats to the Church. In December 1864 Pius condemned these principles in the *Syllabus of Errors*, a summation of 80 principal errors and false doctrines that had been censured in previous papal encyclicals. It included condemnations of rationalism, socialism, communism, secret societies, Bible societies, religious toleration, freedom of conscience and speech, and the separation of church and state. One article condemned the notion that the pontiff should reconcile himself to “progress, liberalism, and modern civilization.” The syllabus was received with zeal by strong Catholic supporters of papal authority and with malicious delight by freethinkers and the republican press. In it the latter found proof of the backwardness of the papacy. The syllabus caused indignation among non-Catholics and confusion among Catholics living in liberal-democratic states who found it difficult to exercise their civic rights and remain obedient to the Church.

The Vatican Council met from December 1869 until September 1870, when the council adjourned without reconvening after an Italian national army entered the city to complete the unification of Italy. Pius opened the council with an address warning of the dangers of liberalism and reaffirming that his temporal authority over Rome was necessary for the maintenance of the Church. Although some feared that the council had been convened to elevate the *Syllabus of Errors* to dogma, the paramount agenda concerned the ecclesiastical authority of the pope. Despite minor opposition from some bishops, the council codified the dogma of papal infallibility. Representing the triumph of ultramontanism, an ideology committed to elevating the authority and power of the pope within the Church, this dogma protected the pope from error when defining any doctrine relating to faith or morals. While the pope was helpless to retain his temporal power in the face of nineteenth-century social and political movements such as liberalism, nationalism, and democracy, his articulation of new dogmas, condemnation of errors and false doctrines, and consolidation of ecclesiastical power ensured the spiritual vitality of Catholicism into the next century.

Catholic Responses to Science and Industrialization—Leo XIII and *Rerum Novarum*

During the nineteenth century, the theory of evolution challenged the faith of Roman Catholics by contradicting the literal account of the

book of Genesis and seemingly questioning the singular importance of the human species. New doctrines such as positivism challenged religious faith by claiming that science and sense experience alone were the only paths to knowledge. At the same time, industrialization focused attention on working-class poverty, deepened class antagonism, and gave rise to the revolutionary ideologies of socialism and communism. To reconcile Catholic thought to modern science and address the social question, Pope Leo XIII (r. 1878–1903) offered Catholic solutions that mediated between the extremes of positivism and antiscience on the one hand and unrestricted capitalism and socialism on the other. His two most important encyclicals, *Aeterni Patris* (1879) and *Rerum Novarum* (1891), suggested how Catholics might engage science and the social question while remaining faithful to the Church.

Aeterni Patris (Of the Eternal Father) encouraged the revival of the Scholastic philosophy of Thomas Aquinas (1225–1274) as a system that could reconcile the Church to modern science. The encyclical described science as a secondary branch of metaphysics and as meaningless outside of its metaphysical context. Scholasticism provided this context by positing God as the ultimate cause of all phenomena and underscoring the belief that scientific investigation and discovery illustrated the magnificence of God's creation. Science was not an end in itself but a means of apprehending and glorifying God. Accordingly, the encyclical maintained that there was no scientific truth that could be inconsistent with the Catholic faith.

Rerum Novarum (Of New Things) addressed the condition of the poor and the working class in industrial society and became the foundation for modern Catholic social thought. The pope condemned both unchecked capitalism and communism, rejecting the former for its amorality and the latter for fomenting class antagonism and for its ultimate goal of the common ownership of property. Although Leo maintained that the state was responsible for ensuring the social welfare of its citizens, he rejected state paternalism as a form of state socialism destructive to the family. He countenanced trade unions and the general

Pope Leo XIII, elected to the papacy in 1878, sought to redefine certain Church teachings to bring them in line with the rapid social, economic and political developments of the nineteenth century. (Library of Congress)

strikes as a last resort but not violence or class war. The encyclical also enumerated the duties of individuals to each other, including patience, fairness, and charity. It also sought to remove the social stigma of poverty, a stigma reinforced by nineteenth-century bourgeois associations of poverty with immorality. Leo reminded laborers of the dignity of work and that poverty was no disgrace in God's eyes. For his sympathy and efforts on behalf of the poor and laboring classes, Leo earned the title of "worker's pope."

Leo's willingness to reconcile science to Catholicism ensured a continuing and fruitful engagement between modern science and the Church. His proposal of a Catholic solution to the social question offered an alternative between ideological extremes and inspired Christian democratic movements that are extant today. Overall, the reforms of Leo XIII helped to

➤ CHRISTIAN DEMOCRACY

This European social and political lay movement, dedicated to improving conditions of the poor and working classes, was founded in response to *Rerum Novarum*. Animated by the Christian duty to realize social justice and to ameliorate poverty, Christian Democracy represented an alternative to liberalism and socialism. Emphasizing the importance of community but acknowledging the worth of the individual, Christian Democrats affirmed the dignity of work and professed respect for law, order, and property rights. European Christian Democrats rejected violence, class warfare, and revolution as means of social reform. Although they accepted social hierarchies, Christian Democracy was open to all members of society regardless of class or confession.

Dutch Reformed Christianity and Afrikaner Identity in South Africa

Afrikaners have been described by various authors as the "white tribe of Africa" in order to reflect both their European origins and their rootedness in Africa. As the offspring of seventeenth-century European colonists—mainly Dutch, French, German and British—who today have no other homeland than Africa, they lead an often ambivalent existence, between African and European. The Dutch, French, and German colonists were welded through intermittent intermingling with indigenous African people into the Afrikaner population of today.

THE CHURCH AT WAR

The Second Anglo-Boer War took place from 1899 to 1902. The British forces could not subdue the Boer commandos who fought a guerrilla war. The Dutch Reformed Church went to battle with the Afrikaner forces in this war. Many Dutch Reformed ministers voluntarily either served as chaplains or actively took part in the fighting. Shared experiences during this war truly welded church and volk (“people”) together as one. Dutch Reformed chaplains also went with the Boer captives to prisoner-of-war camps in Ceylon and India for several years, drawing church and volk, Dutch Reformed Christianity and Afrikaner identity, even closer together.

—Willem Saayman

Yet their lighter skin color and unique language have remained as a reminder of their ambivalent existence. Incipient racism characterized European colonization of the Cape Colony in 1652. European colonists considered themselves to be superior to the indigenous inhabitants as a result of cultural ethnocentrism (determining factors were Christian belief, standards of civilization, and education). Over time a variety of historical factors changed that ethnocentrism into full-blown racism. Thus, racism had been alive and well in South Africa long before the Afrikaners achieved political power over the whole of South Africa in 1910. The first legislative measures that instituted the racist ordering of South African society were indeed formulated and introduced by the colonial government already in the nineteenth century upon instigation by the mining conglomerates, whose ownership was mainly non-Afrikaans. Blacks did not volunteer to work in the mines in sufficient numbers, so measures such as the poll tax had to be instituted to force them into the cash economy. This led to the development of a huge racist, migrant labor industry, which necessitated racist socioeconomic ordering of movement and housing.

Afrikaners also enthusiastically embraced the racist ordering of society, as was especially reflected in the dominant Afrikaner church, the

Dutch Reformed Church. The Dutch Reformed Church instituted racially separated churches for its members and converts toward the middle of the nineteenth century. In Afrikaner minds therefore, racial separation had practical as well as divine sanction. There is thus an inherent correlation between Dutch Reformed Christianity and Afrikaner identity. The racist structuring of the political economy in South Africa was therefore simpler than political expediency; it was considered also as a divine imperative. The already intimate link between the Dutch Reformed Church and Afrikaner people (“volk”) was immensely strengthened as a result of the suffering of Afrikaner people during the Second Anglo-Boer War (1899–1902). This war was intimately linked to the struggle for political hegemony over the mineral resources of southern Africa. In order to win the war, the British forces applied a scorched-earth policy, destroying Afrikaner farmsteads and herding women and children into barbaric concentration camps, where 28,000 (a huge proportion of the Afrikaner population at the time) died. This led to huge losses also in possessions and fixed properties, and it is estimated that Afrikaners in general and the Dutch Reformed Church in particular retained only 5 percent of their farms, manses, and church land. After these traumatic events the Dutch Reformed Church and Afrikaner people were basically one in mind and spirit. The Dutch Reformed Church became the guarantor of the Afrikaans language (with Afrikaans replacing Dutch in church services) and culture (especially Christian National schools). When South Africa became the independent dominion of the Union of South Africa in 1910, it was therefore impossible to describe Afrikaner identity without reference to Dutch Reformed Church spirituality. This link was to grow much stronger in the ensuing decades of the twentieth century.

Mormonism—Founding and Early History

Emerging from the sectarian strife of the Second Great Awakening, the religious revival that swept through much of the United States from around 1800 through the 1830s, the Church of Jesus Christ of Latter-day Saints became the first new religious tradition founded in the United States. It was inspired by Joseph Smith Jr. (1805–1844), whose family moved from Vermont to western New York shortly after his birth. Concerned about finding God’s true church among the contending denominations, as a 14-year-old he retreated to a forest in Palmyra, New York, where he claimed to have a vision of God and Jesus Christ, who instructed him that he would become the instrument by which Christ’s primitive church would be restored to the earth.

Smith claimed to have received additional visions in which he was led to an ancient book of scripture composed of unusual hieroglyphics engraved upon pages of beaten gold. It came to be known as *The Book of Mormon*, named after the ancient Native American prophet who compiled it. Smith dictated a translation of these hieroglyphics over the course of three months. The exact nature of his translating abilities remains controversial. Witness accounts record Smith making translations while looking into a hat that contained a peep stone or seer stone, a folk divination practice once popular in the eastern United States.

The publishing of *The Book of Mormon* in 1830 created immediate controversy with mainstream Protestant sects, which considered his claims heretical. Nonetheless, Smith recruited enough converts to formally establish his “Church of Christ” in April of that year. Eight years later he expanded the name to “The Church of Jesus Christ of Latter-day Saints” to differentiate it from Jesus’s original church. Enemies of the movement took to calling its members Mormons. Despite its pejorative roots, today the church widely accepts the term.

Early Mormon doctrines included a belief that Native Americans were descended from the Tribes of Israel and that Jesus Christ would soon return to America to establish his kingdom

on earth. Latter-day Saints were charged with preparing the way for that return through proselytizing and gathering together to build the utopian City of Zion in Missouri.

Smith’s missionary efforts bore fruit when a community of Christian communalists in Kirtland, Ohio, Alexander Campbell’s Disciples of Christ, converted nearly en masse to Smith’s church during the winter of 1830–1831. Smith in turn embraced the converts’ cooperative economic system and made it a part of his evolving theology. When persecution in New York threatened the fledgling church, Smith moved his community to Kirtland. He then used Ohio as a base to settle near Independence, Missouri. For several years the Latter-day Saints lived in both states.

Smith’s doctrines and practices alienated many Americans. In addition, the Mormon practice of gathering the membership of the church together into distinct communities challenged both the political power and goodwill of the Mormons’ neighbors. They soon found themselves under attack in both Ohio and Missouri. In Missouri, violence peaked in 1838 when Governor Lilburn Boggs declared the Mormons to be in a state of rebellion and ordered them to leave or face extermination. In the ensuing violence, Missouri militia killed all the males of one Mormon community and arrested Smith and other church leaders. Smith and his colleagues escaped execution but were kept for several months in an underground jail in the town of Liberty.

While Smith was in jail, the church moved to a swampy parcel of land on the Illinois bank of the Mississippi River. In 1839, Smith and other leaders escaped from jail and joined the main body of the church in this new town, which they called Nauvoo. In Nauvoo, Smith planned to build his utopia. After securing a town charter from the state legislature, he began to build his dream. Nauvoo flourished, and thousands of converts made their way up the Mississippi River to join the Latter-day Saints. The Mormons continued to attract opposition, however, especially because of their teachings on polygamy. The doctrine of plural marriage had been stated by Smith as early as 1831, although initially

Mormons practiced polygamy in secret and limited its practice to the leadership of the church. When Smith expanded the practice in Illinois, citizens and politicians in Illinois came to view the Mormons as threats to Christianity, family structure, and the social-political order. The Mormons once again faced forced expulsion.

In the spring of 1844, Smith considered Texas, California, and the Oregon Territory as places to relocate his church outside the reach of the federal government. Before any plans could be solidified, Smith destroyed the press of an opposition newspaper that threatened to expose Mormon polygamy. In the ensuing controversy, state militia prepared an assault on Nauvoo to arrest Smith for treason. He surrendered to Illinois authorities in an attempt to deflect violence against his congregation, but while in custody a mob killed the 38-year-old Smith and his brother.

After Smith's death, a succession crisis threatened the survival of the church. Brigham Young, the leader of Smith's Quorum of the Twelve Apostles, eventually assumed leadership. Other leaders also stepped forward, however, and the church splintered. In the winter of 1846, the state militia forced the last Mormons out of Illinois. A majority of the church followed Young into the Salt Lake Valley, which in 1847 was in Mexican territory but in 1848 became part of the United States after the Mexican War. Young and subsequent leaders continued to resist federal authority in the modern state of Utah into the twentieth century. Much of Smith's family remained in the Midwest and reorganized the church under the leadership of Smith's eldest son, Joseph III. This branch of Mormonism recently renamed itself the "Community of Christ" and maintains headquarters in Independence, Missouri.

Muscular Christianity

Muscular Christianity was an international religious movement that helped shape modern ideas of the body, race, and masculinity around the world. Indeed, the popular movements of physical culture, social Darwinism, urban progressivism, and eugenics owe a great deal to this Christian philosophy.

The term "muscular Christianity" first appeared in the 1850s in England to describe the writings of novelists such as Thomas Hughes, who argued that asceticism and effeminate sentimentalism had weakened the Anglican Church. By the turn of the century, muscular Christianity had spread throughout the United States thanks to leaders such as the Social Gospel minister Josiah Strong (1847–1916). The movement's proponents argued that Christians needed to cultivate not only their spiritual and mental strength but also their physical health. To glorify the body was to glorify God. In particular, Anglo-Saxon Christian men had a special responsibility to develop their physiques for the battles of modern life.

The muscular Christianity movement was in large part a cultural response to the social changes of the late nineteenth and early twentieth centuries. In countries such as Britain and the United States, this religious movement stemmed from widespread anxieties over urbanization, industrialism, immigration, and imperial expansion. The increasing movement of rural folk into the cities, as they became the wage-labor workforce for factories, inspired popular theories about the relationship between urban living and the deterioration of human health. Many Christian progressives blamed the high population densities, poor ventilation, rundown housing, and inadequate sanitation of urban areas for sicknesses such as tuberculosis.

Muscular Christianity also addressed the vexing problem of maintaining racial, ethnic, and gender hierarchies in the modern world. Many intellectuals feared that overcivilized white men

► THEODORE ROOSEVELT, “MUSCULAR CHRISTIAN STATESMAN”

At the turn of the twentieth century, Theodore Roosevelt's public words and actions elevated the profile of muscular Christianity by linking ideas of political strength with rugged masculinity in the popular consciousness. Roosevelt had a long-standing fascination with competitive sport and exercise from his days as a Harvard student to his terms as the governor of New York and the president of the United States. After the July 1898 victory over Spanish troops at San Juan Hill, stories of his courageous military leadership of the Rough Riders made him an icon of American manhood. As

a statesman, his interest in physical fighting techniques became intertwined with his views on race and foreign affairs. In the wake of Russia's defeat in the Russo-Japanese War (1904–1905), Roosevelt developed a fascination for the Japanese art of jiu-jitsu. An avid boxer, Roosevelt took lessons from trainer Mike Donovan and even invited World Champion prizefighters for visits to the White House. Roosevelt believed that a national commitment to physical fitness was central to the international future of the United States.

—Theresa Runstedtler

were physically degenerating. G. Stanley Hall, a turn-of-the-century psychologist known for his preoccupation with the decline of old-stock Americans in the face of non-Anglo-Saxon immigration, touted the importance of regular exercise in addition to book learning. Furthermore, many prominent statesmen believed that the white race was literally in danger of dying out, as the population growth of Europe and North America lagged behind that of Asia and Africa. During imperial conflicts such as the Boer War (1899–1902) and the Spanish-American War (1898), the need for robust fighting men became a top priority for Britain and the United States. American president Theodore Roosevelt, an avid sportsman and advocate of the strenuous life, contended that the maintenance of global white control hinged on the development of rugged, virile men.

This cultural climate contributed to the idea that the strength of any nation was dependent on the strength of its individual citizens. White boys and men were encouraged to revisit the primitive elements of physical exertion, competitive sports, and outdoor living. This inspired the expansion of organizations such as the Boy Scouts and the Young Men's Christian Association alongside the first state programs for public health and physical education. Muscular Christianity also laid the foundation for the modern fitness industry. By the early 1900s the profitable business of physical culture had its own

publications (Britain's *Health & Strength* and America's *Physical Culture*) along with its own celebrities, such as German strongman Eugene Sandow and U.S. bodybuilder and publishing magnate Bernarr MacFadden.

Young Men's Christian Association

The Young Men's Christian Association (YMCA) originated in the mid-nineteenth century as a voluntary association to bolster the faith and mold the character of Protestant men and boys

and then evolved into a fee-based membership organization run by paid staff that provided varied services, including physical training, to both sexes and all ages. George Williams formed the first Young Men's Christian Association in 1844 in London, England, banding his fellow clerks together to preserve their faith amid urban temptations. During the early 1850s similar associations sprang up in North American cities, offering prayer meetings, Bible classes, libraries, and literary societies. Although the associations federated at the state and international (U.S. and Canada) levels, each level raised its own budget and remained independent, permitting the wide diversity of local programming that has characterized YMCAs to this day. Since in the nineteenth century even youths in white-collar jobs commonly worked at ages when their twentieth-century counterparts would have been schoolboys, early YMCAs admitted boys in their early teens as full members. By the 1870s, however, as the original members grew older, many YMCAs required a minimum age, usually sixteen.

At first predominantly evangelistic in their approach, YMCA men soon compromised between revivalist and antirevivalist Protestants, continuing to seek conversions but stressing the gradual growth in character preferred by antirevivalists. YMCAs of the 1860s and 1870s broadened their programs, erected buildings to house them, hired professional staff (known as "secretaries"), and defined their mission as improving young men mentally, socially, and physically, as well as spiritually. As a cult of muscular Christianity took hold among white-collar workers who wanted to be good, Christian, respectable, and yet manly, by the 1890s gymnasiums became the main attraction. There young clerks could work off troubling energies and strengthen a sense of masculinity that many argued was diminished by sedentary work, submission to a boss's orders, and the advent of female coworkers. In search of group activities less regimented than calisthenics, YMCA men invented two gymnasium games, basketball in 1891 and volleyball in 1895.

Early YMCA workers held weekly religious meetings and Bible study, often judging success by the numbers of boys who accepted Christ.

On the theory that character required control of all errant impulses, YMCA men put the boys through long gymnastic drills. In the 1890s, though, with the advent of team sports and swimming, recreation began to outweigh disciplinary training. Though both remained important into the 1920s, the balance shifted from conversion toward character building. This developmental approach gained strength around 1900 as boys' work specialists discovered adolescence. The new term, popularized by students of the psychologist G. Stanley Hall (among them Luther Gulick), gave concerns about youth a scientific-sounding rationale. Though a time of crisis when sexual and other new instincts flooded in upon teenagers, adolescence in Hall's view was also an era of great promise when religious conversion and idealistic enthusiasm were natural.

Most YMCA junior members were sons of the middle class. They could afford fees to use the gymnasium and pool, and most were promising recruits for the parent association, since the YMCA's founding fathers had restricted full membership to members of evangelical churches, defined in 1869 to mean orthodox Protestant denominations. Except in smaller northern cities in the United States where African Americans were few, YMCAs were racially segregated, with separate branches operating under black leadership. Despite their anger at white racism, college-educated elites commonly supported black YMCAs as safe public spaces free of white control and devoted to advancement of the young. Starting around the 1920s, the focus of YMCA programming grew more diffuse as local associations enrolled non-Protestants, women and girls, and young boys in addition to the teenage boys and the men of all ages who formed the YMCA's more traditional constituency.

The Second Great Awakening

The First Great Awakening, the wave of religious revivalism of the 1730s and 1740s, had challenged the social order of New England, especially the established clergy, and provided the colonists with a common vocabulary of evangelicalism and millenarianism. By the 1770s much of the evangelical fervor had been subsumed into Patriot rhetoric, a conflation of political rebellion with assurances of God’s favor. Although the revival had sputtered by the middle of the eighteenth century and through the era of the American Revolution, evangelical enthusiasm continued during the final decades of the eighteenth century in the Maritime Provinces of Canada under the direction of Henry Alline and other revivalists. The Second Great Awakening, a series of revivals in the decades surrounding the turn of the nineteenth century, served to further ensconce evangelical Protestantism as the religion of the people. The Second Great Awakening convulsed three regions of the new nation: New England, especially northwestern Connecticut; the Cumberland Valley of Kentucky; and western New York, a region opened to settlement by the Erie Canal.

The religious revival in each region contributed to the Protestant tradition in America. The awakening in the South, also known as the Great Revival, made the camp meeting into an American institution. Building on the Scottish tradition of sacramental seasons, extended gatherings meant to foster piety, camp meetings provided both religious exhortation and social interaction for widely dispersed settlers. Usually marked by

religious enthusiasm, they became (and remain) commonplace, and by 1845 B. W. Gorham even published a camp-meeting manual on how to organize and conduct the events.

The Second Great Awakening in western New York fundamentally recast Protestant theology in America. Whereas the Puritans of New England had been Calvinists firmly committed to the doctrine of predestination, Charles Grandison Finney (1795–1875), a Presbyterian minister in Rochester, New York, and leader of the Second Great Awakening, taught a different theological scheme known as Arminianism, which the Puritans had regarded as heresy. Finney and his followers rejected the notion that God had elected some for salvation and that there was nothing individuals could do on their own to gain entrance into heaven. According to Finney, everyone had equal access to salvation, and salvation itself was merely a matter of individual choice or volition. Finney and other revivalists of his era took it upon themselves to convince and cajole their audiences to convert to evangelical Christianity, something that the Protestant preachers of an earlier era would have found heretical. Among a people who had recently taken their political destiny into their own hands, however, Finney’s assurance that they controlled their spiritual destiny as well proved to be enormously attractive. Revival preachers ever since—from Dwight L. Moody to Aimee Semple McPherson, from Billy Sunday to Billy

A Methodist camp meeting typical of the evangelism of the Second Great Awakening. (Library of Congress)

► CHARLES GRANDISON FINNEY, “WHAT A REVIVAL OF RELIGION IS”

In 1834 Charles Finney delivered a sermon on the need for “religious excitement” as a way to inspire individuals to commit themselves to Christianity. A brief excerpt follows:

“It is altogether improbable that religion will ever make progress among *heathen* nations except through the influence of revivals. The attempt is now making to do it by education, and other cautious and gradual improvements. But so long as the laws of mind remain what they are, it cannot be done in this way. There must be excitement sufficient to wake up the dormant moral powers, and roll back the tide of degradation and sin. And precisely so far as our own land approximates to heathenism, it is impossible for God or man to promote religion in such a state of things but by powerful excitements.—This is evident from the fact that this has always been

the way in which God has done it. . . . For instance, how many there are who know that they ought to be religious, but they are afraid if they become pious they shall be laughed at by their companions. Many are procrastinating repentance, until they are settled in life, or until they have secured some favorite worldly interest. Such persons never will give up their false shame, or relinquish their ambitious schemes, till they are so excited that they cannot contain themselves any longer.”

Graham—have (whether they acknowledged it or not) used Arminian theology to persuade sinners of their need for repentance.

Another legacy of the Second Great Awakening was social reform, a movement associated to some degree with all three theaters of the Awakening but especially with New England. The revival unleashed a great deal of optimism about the perfectibility not only of individuals but also of society. Protestants believed that they could bring on the millennium (1,000 years of righteous rule, predicted in the book of Revelation) through their own efforts. If they worked hard to reform the ills of society—drunkenness, the scourge of slavery, low rates of female literacy—then the millennium would begin here on Earth and, more particularly, in America. Thus, the Second Great Awakening helped inspire feminist, antislavery, and temperance movements, all three of which put their stamp on the development of the new republic.

Social Gospel

Social Gospel was a movement within late-nineteenth- and early-twentieth-century Protestantism that placed pastoral emphasis on social reform. It was largely a response to the formation of large corporations and the accompanying class antagonism. The Social Gospel (also referred to as “social Christianity” or “Christian Socialism”) derived from an intellectual shift within American Protestantism. Prior to the American Civil War, many mainstream

denominations of evangelical Protestants supported an individualistic social ethic and laissez-faire economic policies. The impact of industrial expansion, urbanization, and immigration in the Gilded Age, however, prompted several influential members of the clergy to place less emphasis on creeds, doctrine, and the private, individual salvation of the soul and more emphasis on true charity to address the nation's growing social problems. In part the Social Gospel was an effort to enhance the appeal of Protestantism in large cities where the Catholic Church was popular among the growing immigrant population. The movement also addressed the emerging labor movement and was a response to accusations that religious organizations were more sympathetic to capital than to labor.

The Social Gospel was intellectual in its origins, as liberal church leaders brought the teachings of Jesus to the social and economic questions of the day. The poverty resulting from the Panic of 1873 and the violent strikes during 1877 concerned church people; however, most still viewed trade unions with suspicion and feared state interference in the economy. A moderate approach to change was largely espoused in the book *Working Men and Their Employer* (1876), written by Washington Gladden (1836–1918), a minister who was the first major figure in the Social Gospel movement. He called on workers to unify under Christianity and originally believed that the application of the Golden Rule could bridge the growing divide between capital and labor.

Gladden would eventually advocate state-regulated capitalism, and he would be joined by several dynamic clerical and lay figures who would make the Social Gospel a national movement. Key figures include Josiah Strong, whose book *Our Country: Its Possible Future and Present Crisis* (1885) encouraged Protestants to participate in missionary work to the nation's inner cities and in the American West. The economics profession became part of the Social Gospel movement with the publication of Professor Richard Ely's *The Labor Movement in America* in 1886. Ely was a strong advocate of the right of workers to organize and founded an organization in 1885 rooted in the ideals of

the Social Gospel—the American Economic Association.

Several Social Gospel advocates toured the nation and lectured extensively on labor and social reform, most notably George Herron and William Dwight Porter Bliss. Herron gained fame for a sermon titled “The Message of Jesus for Men of Wealth” (1890). This sermon vilified the acquisition of wealth in the United States. Eventually Herron completely lost confidence in industrial capitalism and established The Kingdom Movement, a brand of social Christianity aimed at establishing “the Kingdom of God” on earth. Bliss, who supported the Knights of Labor, was among the many clergymen influenced by the Nationalist movement spurred by Edward Bellamy's utopian novel *Looking Backward, 2000–1887* (1888). He founded the Society of Christian Socialists and served as the editor of its publication *The Dawn*. The issues addressed in the teachings and writings of Social Gospel supporters were the abolition of child labor, higher wages, a shorter workweek, a living wage, and prison reform.

The Social Gospel fit well with the spirit of the Progressive Era, and its ideas were often reinforced by the exposés of corporate America and the urban slum by the muckraking journalists of the period. In the 1890s, however, the movement began to weaken. The Depression of 1893 led to more radical strains in the Social Gospel movement, and social Christians became more circumspect as labor violence intensified. But before the Social Gospel became passé, its strongest voice would be heard: Walter Rauschenbusch.

A Baptist minister who worked to ease the suffering in New York's Hell's Kitchen, Rauschenbusch eventually gained a reputation as one of America's greatest theologians. His major work, *Christianity and the Social Crisis* (1907), sought to define the role of the church in American society and took the social implications of Christianity to a higher level. Among the ideas advocated by Rauschenbusch were public ownership of utilities and transportation and redistribution of land to improve housing conditions for workers. Rauschenbusch's ideas brought about renewed interest in the Social

Gospel and prompted most mainline Protestant churches to adopt the *Social Creed of the Churches* in 1908. This document committed the churches to work in support of a wide range of reforms on behalf of the working class. The Social Gospel declined as the curtain fell on the Progressive Era and with the passing of Rauschenbusch and Gladden in 1918; however the spirit of the movement lived on in the twentieth century in the work of many social reformers.

■ Introduction: Christian Missionary Endeavors in Africa and Asia

By the late 1700s the surge in missionary activity that had accompanied Europe’s worldwide expansion in the sixteenth and early seventeenth centuries had run its course. Around 1800 only a few missionaries were active in China, India, the East Indies, and the Pacific islands, and none at all were active in Japan, Korea, and the interior of Africa. Much changed in the next 100 years. In 1910, 1,200 delegates representing 160 Protestant missionary boards and societies attended the World Missionary Conference in Edinburgh, Scotland; their slogan was “the evangelization of the world in this generation.” The delegates heard a series of upbeat reports on the activities of thousands of well-funded and highly educated missionaries who had founded mission stations, schools, and medical clinics throughout Africa and Asia, translated the Bible into all the world’s major languages and many minor ones, and had converted hundreds of thousands to Christianity. Considering that Roman Catholics and Russian Orthodox Christians also experienced an upsurge in missionary activity in the nineteenth century, the hope of “evangelizing the world in a generation” might have been somewhat less unrealistic than it might seem.

The origins of the modern missionary movement can be traced back to eighteenth-century

Protestant evangelical movements that resulted in the founding of the Methodist Church in England, the Great Awakening in the United States, and the growth of Pietism among Lutherans in Germany and other parts of northern Europe. These movements all emphasized the gospels as a source of inspiration and the centrality of personal conversion (being “born again”) in the life of Christians. Having experienced transformation in their own lives, evangelicals were eager to share the “good news” of Christ with others. Many also became social activists. Quakers, Methodists, Baptists, and evangelicals in the Church of England, for example, were the driving force behind the abolitionist movement in England beginning in the 1780s.

The result was an upsurge of missionary activity in the 1790s and the first decade of the 1800s. In England, the Baptist Missionary Society was founded in 1792, followed by the London Missionary Society (1795) and the Church Missionary Society (1799). State missionary societies founded in New York, Connecticut, and Massachusetts came under the umbrella of the American Board for the Commissioners of Foreign Missions in 1810. German Lutherans founded a school in Berlin for training missionaries in 1800 and formed the Basel Mission in 1815. By then, missionaries supported by these

societies had taken up their work in India, China, the East Indies, and parts of Africa.

Enthusiasm for missionary work was not limited to Protestants. The upsurge in Catholic piety following the French Revolution inspired a rededication to missions work on the part of older religious orders such as the Franciscans, Benedictines, and Jesuits (reestablished in 1814 after having been dissolved in 1773); it also led to the founding of many new religious orders specifically dedicated to missionary work. Even the Orthodox Church of Russia increased its missionary activity, with its missionaries active in Siberia, China, Japan, the Middle East, Alaska, and California.

Missionaries are sometimes depicted as little more than cat's-paws for nineteenth-century imperialists, who used them to provide moral cover for what was essentially an exercise in power politics and economic exploitation. True, the French government used the persecution of Catholics and Catholic missionaries as a pretext for their invasion of Vietnam in 1858. And it is also true that missionaries and missionary societies strongly supported colonial enterprises. They benefited from the protection offered by colonial administrations and the favorable treaties that Western imperialists imposed on foreign governments. But missionaries received little in the way of government subsidies; their efforts were sustained mainly by large and small donations from countless individuals who dreamed of winning the world for Christ.

The missionaries' efforts, which took them to places as different as China, the Muslim Middle East, and tribal New Guinea, varied greatly but they shared a number of common characteristics. Many missionaries translated the Bible into foreign languages, not a few of which were obscure by European standards. William Carey, an English cobbler who became the first British missionary to India in 1793, translated the Bible into Bengali and no less than 24 other Indian languages and dialects. Women played key roles in nineteenth-century missionary work, both at home, where they often were leaders of their congregations' missionary societies, and in the field, where as missionary wives, single women, or members of Catholic religious orders they served as teachers, nurses, and active

missionaries. Many missionaries experienced great hardship. In rural areas mission stations at first often amounted to little more than a simple cottage, a few outbuildings, a chapel, and perhaps a medical facility and a school. Missionaries suffered from disease, homesickness, frustration, and hostility; not a few were murdered by those they sought to convert. They were, however, unwavering in their conviction that they were doing God's work, not only by converting nonbelievers but also by drawing them away from heathen practices and civilizing them by introducing Western ideas of proper dress and acceptable sexual behavior.

If the missionaries' goal was indeed to "win the world for Christ," then of course they failed. They made few converts among Muslims in either Africa or Asia, and although many upper-class Japanese, Indians, and Chinese eagerly took advantage of the education offered by missionary schools, relatively few converted. In 1890 there were 1,600 Protestant missionaries in China but only 37,000 Chinese Protestants compared to a half a million Chinese Catholics. In India, those who converted largely were drawn from the lowest castes or tribal peoples who had never been absorbed into Hindu culture. Some estimates for the early 1900s place the number of Christians in India at two million Catholics and one million Protestants, but these figures include regions where Christianity had been established before the 1800s and are probably inflated. In terms of percentages, the missionaries' greatest success rate came in Oceania, where small island populations, made smaller by Western diseases and exploitation, often were brought into the fold after the conversion of a major chief or king. In the long run, the missionaries' greatest achievement came in Africa, where Christianity today is the majority religion in most countries south of the Sudan. In 1900, however, a religious map of Africa would have shown that outside Muslim areas, most Africans still adhered to traditional religions despite Christian gains in the Gold Coast, Liberia, Sierra Leone, Uganda, and South Africa. African Christianity's growth came mainly in the twentieth century.

Wherever they went, missionaries had an impact beyond the sphere of religion.

Protestant missionaries in the Congo Free State played a key role in revealing the atrocities of Belgian king Leopold II's regime in the 1890s and early 1900s. Many worked to improve the status of women and girls by lending support to movements to end foot binding in China, sati in India, and female circumcision in Africa. In many regions, medical missionaries provided improved care and introduced modern ideas about sanitation and personal hygiene. Above all else, they served as educators. They founded many hundreds of schools and colleges that provided students training in subjects ranging from basic literacy and farming techniques to Western science, foreign languages, and history. Not all students became Christians, but all were transformed by their newly learned skills, and perspectives.

—James H. Overfield

Protestant Missions in Africa

The second half of the eighteenth century witnessed a dramatic increase in missionary activities in sub-Saharan Africa, where efforts over the following century or more were closely linked with European trade and colonialism. The evangelical revival movement among English and German Protestants in the eighteenth century intersected with the abolitionist work of Christian and other philanthropic groups, contributing to greater interest in Africa and the world. Yielding relatively few converts in their early efforts, the missionaries nonetheless had a large impact, shaping African cultures and societies during tumultuous times.

The missionary presence made early and important inroads in West Africa among the populations of recaptured slaves transported into Sierra Leone beginning about 1792. From its base in Sierra Leone, the Church Missionary Society (more commonly known as the Church Mission Society, or CMS) disseminated evangelized Africans to other regions in the nineteenth century. Among the slaves on a Portuguese ship captured by the British Royal Navy in 1821, Samuel Ajayi Crowther was taken to Freetown, Sierra Leone, where he was released and eventually converted to Christianity. Crowther was educated by the Church Missionary Society and eventually moved to London for further education. In 1841 he accompanied the missionary J. F. Schon on an expedition to the Niger. Crowther was ordained a priest in 1843. In addition to his evangelical work, he studied several African languages, translated the Bible into Yoruba, and eventually established a mission at Abeokuta, his native town. He became the first African bishop in 1864.

Missionaries often arrived in Africa at the invitation of foreign merchants and their governments. The network of mission stations furthered the demand for and distribution of imported goods. Missionaries built houses on leased land and modeled the moral behavior they derived from European cultural backgrounds. Their efforts were financially supported from overseas donations, grants from colonial governments, and local collections.

Transatlantic connections played a special role after the abolition of the slave trade by Great Britain and the United States (1807) and the

SCOTTISH PRESBYTERIAN MISSIONARY MARY SLESSOR

The Nigerian novelist Chinua Achebe, the son of a teacher in a missionary school, credits the missionaries in his classic novel *Things Fall Apart* (1959) for having brought not only religion but also government to Nigeria. Some foreign missionaries, such as Mary Slessor, who worked in southeastern Nigeria between 1876 and 1915, were convinced that their efforts both benefited from and contributed to colonialism. Slessor's

knowledge of local languages and cultures allowed her to play an intermediary role between the British colonial officers and Africans even to the extreme of being given a judicial appointment in the native court system. Yet after the first 15 years of missionary work, Slessor could count only 7 adults and 11 children as baptized converts.

—Candice Goucher and Cherri Wemlinger

founding of the American Board of Commissioners for Foreign Missions (1810). Fueled by Pan-African radicalism, the later evangelical efforts of some Africans helped transform Christianity and the continent in the twentieth century. John Chilembwe (1871–1915) was an independent church leader, attending first a Presbyterian mission in central Africa and later a black Baptist seminary in Lynchburg, Virginia. Chilembwe eventually established the Providence Industrial Mission in Chiradzulu (Malawi) and inspired anticolonial resistance (1914–1915) from which Malawi nationalism emerged.

Both medical institutions and Western schools were pioneered by Protestant missionaries, who introduced and fostered formal education on the African continent in South Africa (1803), Gambia (1826), and Nigeria (1842). Education, viewed as a primary mechanism for gaining converts, was initially aimed at African men. When women were permitted to attend mission schools, their curricular content differed markedly, with its emphasis on domestic ideals. The focus eventually shifted to children, with the Basel Mission and Wesleyans building more than 400 schools prior to 1910, when the first colonial government schools opened. In general, the evangelical path that began with the nineteenth-century translation of the Bible, hymnals, and scripture not only contributed to the forces of Westernization but also furthered African agency.

Theological Debates in Ethiopian Christianity

During Africa's long period of contact with Europe, Ethiopia, along with Liberia, remained politically independent from Western powers. Ethiopians also sought to preserve the unique theological perspectives of their Christian faith. One of the original centers of Christianity, the Ethiopian Church is historically monophysite ("one nature"), maintaining that Jesus of Nazareth had only a divine nature and not an

additional human nature. Theologians argued that while Jesus of Nazareth was composed of two natures, at the Incarnation his "finite drop" of humanity was swallowed up by the "infinite ocean" of his deity. Opposed by the ecumenical formula framed at the Council at Chalcedon (451) that Jesus was "one person *in* two natures," the Ethiopian Church broke away from Western Christianity and asserted its own orthodoxy. The resulting Ethiopian Orthodox Church remained unaffected by Western religion until the controversies provoked by eighteenth-century Jesuit and nineteenth-century Protestant missionaries, from which emerged fertile soil for new developments in the twentieth century.

For the Roman Catholic Jesuits, who were active as missionaries in Ethiopia from 1555 until they were expelled in 1634, eliminating the Ethiopian Christological divergence was a major goal. But the endeavor backfired, further entrenching the majority of Ethiopian Christians in Tewahedo (official Monophysitism) and stimulating two sizable splinter groups to formulate new Christologies that understood Jesus in ways that differed from Tewahedo and Chalcedon. The Qebat ("Anointing") Christology, devised by teachers from the province of Gojjam, alleged that a solely divine Jesus became a perfect man and perfect Savior when the Holy Spirit anointed him at his baptism. Hence, the Qebat school instructs adherents to pattern their lives upon Jesus's public ministry, thereby empowering them to perform such miraculous healings and exorcisms as the Gospels report. Conversely, Gondar Christology, named for its city of origin and attaining popularity in monastic centers, claimed that Christ was only human by nature until he was deified at the Jordan River through a special act of divine grace. Here the religious motive was moral imitation, leading to transformation: by leading the same type of virtuous yet normal human life that the prebaptismal Jesus led, one will likewise attain conversion of one's nature and receive divine sonship. Despite their differences, both the Qebat and Gondar schools leave open a "purely human window" at some stage of Jesus's career, thus affording Ethiopians a model for daily living unavailable with the exclusively divine and so inimitable Christ of the Ethiopian Orthodox.

The nineteenth-century Protestant missionaries' emphasis on original sin and salvation by grace through faith alone counterproductively pushed a native Church desiring freedom from foreign domination to opposite ends of the theological spectrum. From its inception the Ethiopian Orthodox Church had found no need to fashion precise doctrines of human sinfulness or salvation but affirmed both as generalities to be given substance by each believer. However, reacting against the Protestant encounter, the Church objected to any interpretation of Genesis or the Pauline Epistles promoting original sin or absolving individuals of responsibility for their own wrongdoings. Similarly distancing itself from the Protestant focus on faith, the Church argued that although Christ's death was necessary for humanity to be redeemed from damnation, anyone desiring salvation must then appropriate Christ's atonement by keeping the Ten Commandments. Consequently, a marriage of orthopraxy ("right action") and orthodoxy emerged by the turn of the twentieth century, which has led some historians to profitably compare Ethiopian Christianity to the diversity of Anabaptist groups that analogously responded to Protestantism in the sixteenth century.

Christian Missionary Efforts in India under Company Rule—Late 1700s to Mid-1800s

As the East India Company solidified its power in India, company officials were confronted by British Christian missionaries who wanted to convert Indians in company territory. Christianity had long been part of India's religious diversity. Thomas or Syrian Christians believe themselves

to be descendents of St. Thomas, one of Jesus's 12 disciples, who they claimed arrived in southern India around 52 CE. However, with the arrival of Europeans in the fifteenth century, efforts to spread Christianity greatly intensified. At the end of the eighteenth century an evangelical movement was sweeping Britain and the United States. In Britain, William Carey (1761–1834), the "Father of the Modern Missionary Movement," argued that Christians were obligated to spread the gospel even to the most remote areas of the world. In response, several missionary societies, including the Baptist Missionary Society, founded in 1792, and the Missionary Society, founded in 1795 (later the London Missionary Society), formed and sent missionaries around the world. Despite this religious fervor in England, company officials were concerned that missionary activity in India would engender hostility among the Indian populace and thus threaten profits and security, so they barred missionaries from India, stirring debates about the role of religion in the territories that the company controlled.

British missionaries were eager to join Portuguese, Dutch, and German missionaries who already had found some success in southern India. However, the company, keenly aware that its power hinged on the support of Hindu elites, would not allow missionaries into its territory. The company feared that missionaries would stir up religious hostility, leading to violence and unrest that would compromise its profits and authority. British missionaries wishing to proselytize were only able to gain entry to company territory by subterfuge or with the help of sympathetic Christians in the company.

At the turn of the nineteenth century missionary societies and powerful men in Parliament and on the Court of Directors (the East India Company's executive body of 24 directors elected from and by shareholders) united to change company policy. They argued that Christianity would not threaten company rule; rather, Christianity would strengthen company rule by making Indians more susceptible to British influence. These directors gained a powerful ally in Parliament member William Wilberforce (1759–1833), who also worked to abolish the British slave trade. In 1813 when the company's charter

came up for renewal, the new Charter Act included a “Pious Clause,” which granted missionaries entry into company territory. However, the company was still apprehensive of missionaries’ presence. To neutralize the threat, the company ignored calls by missionaries to abolish the indigenous practices of widow burning and child marriage. Still, missionaries continued to arrive in India, founding schools, colleges, and hospitals and advocating women’s rights.

Missionary efforts under company rule had mixed results. Missionaries found success among tribal groups not yet reached by Hinduism or Islam and among lower castes whom missionaries promised to save from what Europeans perceived as Hindu oppression. Despite these successes, company fears about missionaries were not unfounded. In 1806 sepoys (Indian soldiers in the employ of the East India Company) stationed at the fortress of Vellore revolted against British officers. We cannot be certain about the origins of this revolt, but many company officials believed that the violence was in part a response to changes in the Code of Military Regulations—specifically the design of a new turban (which included leather) as well as the belts on the uniform front that resembled a cross in addition to regulations concerning facial hair and a ban on caste marks and earrings—all of which the public interpreted as an attack on traditions combined with an apparent embrace of and possible forced conversion to Christianity.

The debate about missionaries in India reveals the ambiguity about the roles of religion and the company in India. Evangelicals insisted that Christianity bolstered company authority, while company officials believed that Christianity endangered British rule. Nevertheless, despite the company’s grave concerns about religion, it appears that secular forces largely destroyed company power. In England debates surged about whether the primary purpose of the company was profit, the salvation of Indians, or the acquisition of new territories and natural resources. Dissatisfaction with the company’s conduct and expenditures and growing concerns about who should regulate the company’s actions helped lead to the British Crown dissolving the company in 1858 following another far

➤ WILLIAM CAREY

William Carey, the “Father of the Modern Missionary Movement,” helped ignite evangelic fervor in Britain at the turn of the nineteenth century. In 1792 Carey published *An Enquiry into the Obligations of Christians to Use Means for the Conversion of Heathens*, which led to the formation of the Baptist Missionary Society. Because the East India Company would not allow missionary activity in its territory, Carey stealthily gained entry to India aboard a Danish ship in 1793. There he taught Indian languages at Fort William College in Calcutta and translated the Bible into Bengali. Carey helped establish the modern missionary movement’s emphasis on spreading Christianity throughout the world in colloquial tongues.

Christian Missions in Nineteenth-Century China

One of the most remarkable cross-cultural exchanges in nineteenth-century China resulted from the increased presence of Catholic and Protestant missionaries. The Italian Jesuit missionary Matteo Ricci began the first Catholic mission in China in the 1580s. Ricci and other Jesuits sought to impress the Chinese elite with their knowledge of geography, science, engineering, and mathematics and were willing to allow Chinese converts to continue some of their traditional Confucian rites. Later, in the seventeenth century, members of the Franciscan and

▶ TIMOTHY RICHARD

Timothy Richard (1845–1919), a Baptist Missionary Society missionary to China, was born in south Wales. In 1870 he worked in Shangdong province (China), where he developed theories of evangelism that depended on social gospel rather than direct preaching. He was secretary of the Christian Literature Society in 1891. The literary output of the society was so prodigious that it influenced leading Chinese reformers Kang Youwei and Liang Qichao. Through personal friendships with them, Richard was able to persuade the Qing court to launch the 1898 Reform Movement. He retired in 1915, but his Chinese name, Li Ti-motai, remained on people's lips throughout China.

—Yuen Lee

Dominican orders took their message directly to the common people and required those who converted to abandon any rite or ceremony connected with Confucianism. In the eighteenth century, in response to the squabbling among the Catholic orders, decisions by the pope in 1715 and 1742 to side with Dominicans and Franciscans on the issue of rites, and the hostility of a number of Confucian intellectuals, the Qing government began to suppress Christianity and limit missionary activity.

In the 1800s, however, missionary activity revived. The first Protestant missionary, Robert Morrison of the London Missionary Society, arrived in Guangzhou and Macao in 1807, and in 1830 the first American missionaries, sponsored by the American Board of Commissioners for Foreign Missions, arrived in Guangzhou. Before the 1840s, however, Christian missionary activity remained illegal.

This changed after the Chinese defeat in the Opium War (1839–1842), as a weakened Chinese government was forced to gradually lift its ban on foreign missionary work. Many Protestant denominations, both American and European, sent missionaries to China, but they numbered only approximately 350 by 1870 and had made fewer than 6,000 converts. Reflecting its much longer presence in China, by the 1870s the Catholic Church claimed approximately 400,000

converts. By 1900, however, the number of Protestant missionaries had grown to 3,445.

Christianity's growing presence in China led to opposition especially among members of the scholar-gentry class, who believed that the missionaries' doctrines threatened Confucian beliefs; they also considered the missionaries themselves as competitors in the functions such as famine relief, teaching, and orphan care that traditionally had been the gentry's responsibility. Many Chinese also came to view Christianity as politically dangerous especially after the Taiping Rebellion (1851–1864), whose leader Hong Xiuquan drew some of his teachings from his understanding of Christianity. Others believed in charges that Christians indulged in promiscuous sex and committed atrocities such as gouging out the eyes of dying persons for use in magic. Conservatives resented some missionaries' criticisms of social customs such as foot binding, polygamy, fortune telling, and child marriages. Ongoing tensions resulted in attacks on missionaries, such as the Tianjin Massacre (1870) in which a mob destroyed a Catholic mission and murdered 21 foreigners, including 10 nuns. Anti-Christian hostility also contributed to the Boxer Rebellion (1889–1901) in which thousands of Christian converts were killed.

Despite the missionaries' efforts, by 1910 only about 1 million Chinese had converted to Christianity, and many of these were so-called rice Christians, who supposedly converted only so they could receive handouts of food. Nonetheless, missionary activities had wide-ranging impact. Their schools and medical clinics helped introduce Western science and learning to China, and many Chinese nationalist leaders of the early twentieth century were graduates of mission schools.

Christian Missions in New Zealand and Australia

After an initial period of failure in the late eighteenth century, Protestant and Catholic missionaries created a number of Christian congregations among the natives and the British settlers of Australia and New Zealand. The leaders of the various churches in Britain and the United States expected to see their version of Christianity transplanted in those colonies. Between 1788 and the 1880s, however, the conditions that the missionaries encountered in the Antipodes laid the groundwork for a unique religious culture.

The first Christian minister came to Australia in 1788 with the First Fleet, the initial contingent of administrators, soldiers, and convicts who settled in New South Wales. The experiences of that Church of England (Anglican) minister, Richard Johnson, were representative of the trials faced by many of the early Protestant

missionaries in the colony. Johnson found it difficult to make much of an impact on either the convicts or their keepers. Regular church services were poorly attended, and in the early 1790s some convicts burned down the settlement's first chapel. For their part, the Aborigines, suffering from European diseases and violence, were wary of the settlers. As a result, Johnson gained little, if any, understanding of Aboriginal culture, and because his other duties in the new colony kept him from embarking on sustained missionary work, he had no success in converting them to Christianity.

This situation began to change when Johnson's successor, Samuel Marsden, arrived in Australia in 1794. Marsden threw himself into mission work, particularly among the Aborigines and the Maori of New Zealand. He adopted an Aboriginal boy and hired several of the boy's tribesmen as servants in the belief that contact with British society would lead to conversion. The plan failed, and the Aborigines eventually returned to their former way of life. Not easily discouraged, Marsden turned his attention to the New Zealand Maori. With the help of the Church

► WILLIAM WHITE AND THE MAORI

The career of the British Wesleyan missionary William White makes one point clear: Christian missions in New Zealand involved more than Europeans imposing their beliefs on the natives. A stubborn and temperamental man, White arrived in New Zealand in 1823 not well suited to the work of converting the Maori. He was unwilling to compromise and flew into rages when he encountered opposition. White's personality contributed to the failure of the first Methodist missions in the colony. After a trip to Britain, he returned to New Zealand in 1830. Then the real trouble began. Maori leaders at the Methodist mission at Hokianga asked White to help keep at bay a group of land-hungry settlers who wanted to exploit the area's rich timber resources. In response White, who believed that the settlers and their alcohol were bad influences on the Maori, decided to ignore the British Methodist Church's rules against missionaries buying land and engaging in commercial activity. Using his own

money, he purchased the best land around the mission, returned it to the Maori, and attempted to recoup his investment by selling timber cut by native converts. The settlers were outraged by this Maori-missionary alliance. The affair ended badly. White, with the support of 500 Maori, threatened to impose a set of laws of his own devising on the settlers that would restrict their access to any remaining land around Hokianga. The settlers responded by complaining to the Methodist authorities in Britain, charging that White had committed adultery with Maori women. The Methodist Church in Britain, bowing to pressure from the settlers, recalled White and removed him from the ministry, though less due to the allegations of adultery, for which there was little proof, than for his land purchases and commercial activity on behalf of the Maori. A little Christianity had turned out to be a dangerous thing in New Zealand.

—Todd Webb

Missionary Society in Britain, he established a mission in New Zealand at the Bay of Islands in 1814. Missionaries from other denominations, both Protestant and Catholic, followed Marsden's lead: the Methodists came in 1823, and the Roman Catholics came in 1838. Unlike the Aborigines, the Maori proved open to the preaching of the newcomers. The Maori gods seemed helpless in the face of British diseases and weapons. Many converts hoped that the Christian God would serve them better. They also adapted Christianity to their own purposes. Beginning in 1864, for example, the King Movement, led by Te Ua Haumene, drew on Christian ideas to rally the Maori in an effort to resist the confiscation of their land, proclaiming that angels would drive the European settlers out of New Zealand.

As the missions to the Maori forged ahead after 1814, the religious landscape of Australia became more complex. Other Protestant denominations, besides the state-supported Church of England, began putting down roots in the colonies. The Methodists, for example, attempted to establish missions among the Aborigines in the 1820s and again in the 1840s, though neither effort proved successful. The Methodists had a more significant impact among those convicts and former convicts who distrusted the Church of England's connection with the state that had consigned them to Australia. Methodism offered such men and women the opportunity to be Protestant without being Anglican. For the growing number of Irish Catholic convicts, however, neither of those options was appealing. In 1820 the British government responded to that section of the colonial population by permitting Governor Lachlan Macquarie to appoint Catholic chaplains, but not priests, from among its ranks. A legally sanctioned form of religious pluralism had been established in Australia almost a decade before it came into existence in Britain.

Religious diversity in Australia increased as the nineteenth century progressed. The papacy appointed its first English bishop since the sixteenth century to oversee the growing Catholic population in Australia. In the 1830s and 1840s, at the urging of colonial politicians, the British state passed a series of Church Acts that provided financial support not just to the Church of England, as was the case in the home country,

but to all the mainstream Christian denominations in Australia, including Roman Catholicism. The Mormon Church, which was officially established in Australia in 1851 with the arrival of two missionaries from the United States, did not share in this largesse. Due to the vicious attacks that newspapers made on Mormon doctrine, which editors considered heretical, Mormonism grew slowly in the colony. Mormon missionaries, working in pairs, had more success in New Zealand. They established a mission there in 1854 and converted 811 Maori between 1881 and 1884 thanks to an 1881 native prophecy that foresaw the arrival of ministers preaching the word of God in teams of two. By the last decades of the nineteenth century, the story of Christianity in Australia and New Zealand was dominated by the development of denominations that were shaped by both their local contexts and the efforts of missionaries from overseas.

Christian Missions in the Pacific Islands

Christian missionary efforts in Oceania date back to the 1600s, when Spanish Jesuits sought converts in the Mariana Islands. Christianity made little progress in the region until the nineteenth century, when not just Catholics but also Protestants from both sides of the Atlantic and Mormons from the United States entered the region in large numbers. With protection from newly established colonial administrations and the support of missionary societies in Europe and the United States, they made Christianity

the dominant religion in the Pacific islands and had a lasting influence on culture and education.

There were several primary Catholic agencies responsible for missionary activity in the Pacific region. The Congregation of the Sacred Hearts of Jesus and Mary (the members of this order who were priests were known as the Picpus Fathers), which was founded in Paris in 1800, was given oversight of the eastern Pacific in 1835. Also in 1835 the Society of Mary, which had been founded in Lyons in 1816, was given oversight of the western Pacific. The Missionaries of the Sacred Heart of Jesus, which was also founded in nineteenth-century France, arrived at New Britain (now part of Papua New Guinea) in 1881. Key Protestant organizations included the London Missionary Society (although founded in 1795 by evangelical Anglicans and dissenting Protestants, the London Missionary Society is not affiliated with a single church), the Church Missionary Society (founded by the Anglican Church in 1799), the Wesleyan Methodist Missionary Society (founded in 1786), and the American Board of Commissioners for Foreign Missions (begun in 1810 and chartered in 1812 by American Congregationalists, though it operated as an interdenominational agency). The Church of Jesus Christ of Latter Day Saints (Mormons) began their missionary effort in the Pacific in 1844. While there was some competition among the denominations, no major conflicts occurred. In fact, the Protestant missionary agencies generally allowed each other separate regions of influence with some cooperative effort across agency lines (e.g., William Ellis of the London Missionary Society leaving Tahiti to spend time in Hawaii working with missionaries of the American Board of Commissioners for Foreign Mission in the 1820s).

A key element in achieving conversions was the ability to translate the message of Christianity into the language of the people. This required the reduction of purely oral languages into written texts that allowed the Bible (especially for the Protestants) and other liturgical materials (especially for the Catholics) to be published on the printing presses brought by the missionaries. This move toward literacy required the Protestants, Catholics, and Mormons to set up schools to teach reading and writing as well as religion. American and European

MISSIONARY MOTIVATION

Missionaries had many different motivations. Here one American Board of Commissioners for Foreign Missions missionary, Sheldon Dibble, who went to Hawaii in 1831 and died there in 1845, explains his motivation to potential missionary candidates back home:

“Both Scripture and common sense, then, concur in establishing the sentiment: *that if our fellow men are perishing, and we neglect to do what we can to save them, we are guilty of their blood.* But, if this doctrine be true, its application to Christians, in the relation which they sustain to the heathen world, is irresistibly conclusive and awfully momentous. The soul shudders, and shrinks back from the fearful thought: IF SIX HUNDRED MILLIONS OF OUR RACE ARE SINKING TO PERDITION, AND WE NEGLECT TO DO WHAT WE CAN TO SAVE THEM, WE SHALL BE FOUND ACCOUNTABLE FOR THEIR ETERNAL AGONIES.”

—Gene Mills

Sheldon Dibble, *Voice from Abroad, or Thoughts on Missions, from a Missionary to his Class-mates* (Lahainaluna, HI: Press of the Mission Seminary, 1844), 31–32.

missionaries both believed that spiritual conversion went hand in hand with the task of “civilizing” the native society. To their understanding, a civilization that looked much like Europe or the United States with literate populations, rational philosophies, and technologies built upon empirical science was the natural outcome of the presence of Christianity. They also believed that the “primitive” cultures represented on the islands were evidence of the spiritual darkness of the islanders, which had to be transformed by teaching not just literacy but also Western agricultural methods, carpentry, and the printing trade. In some cases, especially evident at the Chiefs’ Children’s School in Hawaii, Western political theory was wedded to Protestant Christianity in an effort to train the future island leaders to reign within a global society.

The missionaries in cooperation with the converted indigenous leaders also banned certain cultural elements that were considered

pagan, offensive, or primitive. For example, the hula in Hawaii was banned for both its connection with religious practice and for its sensuality. Likewise, restriction and cultural transformation came regarding dress and sexual mores. The European explorers and seamen of the first generation of contact were routinely greeted by mostly naked island women swimming to their ships with the hope of garnering some of the personal *mana* (spiritual power) of the visitors through sexual relations. Missionaries steeped in Victorian morality and puritanical religion could not abide by these practices and manipulated the acceptance of Euro-American dress styles and the decline of the socially accepted free practice of sexuality. While much of the traditional cultures remained under the surface, with traditional healing rituals conducted by *kahunas*, shamans, or priests continuing in the remote villages, the public life of most Pacific islanders was one of compromise and cultural attrition.

In many cases the missionaries sought first to convert island leaders, believing that if they converted, the majority of the people would follow. This practice achieved a measure of success, with the capstone being the Sandwich Islands Mission in Hawaii, where the missionaries developed close relationships with the *ali'i*. For example, in the 1820s Kaahumanu, the queen regent, and Kalanimoku, the prime minister, gave the missionaries immediate inroads into the broader community, especially as the leaders came to the defense of the missionaries and their moral laws concerning dress style, the ban of alcohol, and chastity. Christian missionary work in the Pacific was not limited to Europeans and Americans but also included Pacific islander converts, who were also welcomed as assistants to the white missionaries as well as pastors on their own in limited circumstances. Prime examples of this are the

missions in the 1850s of the Protestants from Hawaii to the Marquesas and Micronesia, where native Hawaiians worked with the American clergy to both evangelize and serve as pastors. In the Pacific, the Catholics engaged the local people as *katekita* (catechists) and *minita* (ministers). In 1822 Auna and Matatore were sent from Huahine to the Marquesas as missionaries, in part because of the skill of their wives in the ministry. Since the 1870s hundreds of South Sea Islander Christians have journeyed to Papua New Guinea as missionaries.

During the second half of the nineteenth century missionary societies gradually withdrew as the predominant presence of Christianity in the Pacific islands. Nevertheless, due to their efforts Christianity became the most prevalent religion in the Pacific, as the self-supporting churches of the white settlers remained, as did the numerous indigenous-led churches that were similar to them in form and doctrine in varying degrees.

■ Introduction: Thought and Religion in South and East Asia

The period from 1750 to 1914 was an era of deep, wide-ranging changes in Asian thought and, to a somewhat lesser degree, religion. Although all of Asia was affected, the changes were most profound in China and

India, the world's two most populous polities, and in Japan, which suddenly emerged in the late 1800s as a regional and emerging world power. Many factors contributed to the region's intellectual and religious transformations, but

the most important was the influence of the West, whose representatives came as threats, conquerors, and a source of new ideas.

Intellectual and religious stirrings are first detectable in India, especially those parts of the subcontinent that came under British East India Company rule. From the time the Company gained control of Bengal in 1760s, its officials realized that its ability to administer their lands and collect revenues depended on knowledge of local customs and legal codes. This in turn created a need to learn Persian, the administrative language of the Mughal empire, and Sanskrit, the ancient language of India in which its legal codes and major religious texts were written. Warren Hastings, the first governor-general of Bengal, encouraged collaboration between Hindu and British scholars and was instrumental in founding the Asiatic Society of Bengal, which in 1784 became the first scholarly society of India. William Jones (1746–1794), who mastered Sanskrit, Arabic, and Persian, and became a great admirer of ancient India, a civilization he considered the near equal of ancient Greece, became the most prominent British “Orientalist.” Indian scholars collaborated with British teachers and students as faculty members at Fort William College, founded in 1800 by the company, to introduce company functionaries to India’s languages and cultural heritage. They also played a role in the founding in 1817 of the Hindu College in Kolkata (Calcutta), which taught upper-class Bengal children some traditional Indian subjects but mainly concentrated on Western literature, history, and science. These were the beginnings of what is often referred to as the Hindu Renaissance.

Unlike the British Orientalists, who had a positive view of Indian culture, the European missionaries who began arriving in the 1790s thought differently. They saw Hinduism as a hodgepodge of superstitious beliefs and practices that consigned Indians to perpetual backwardness. Despite such reservations, the missionaries contributed to India’s intellectual and religious development in a number of ways. They established printing presses in many cities and encouraged the use of vernacular languages by translating the Bible and other works into Indian tongues. They also made a major contribution in the area of education by founding numerous primary and secondary schools. These

missionary schools laid the foundation for the technological schools and universities founded under the auspices of the colonial administration from the 1850s onward. Finally, the criticism leveled at Hinduism by missionaries (and some British officials) caused Hindu intellectuals to launch a spirited and productive reexamination of India’s religious rites and values, with some of them freely drawing on beliefs and ethical values of Christianity and others staunchly defending ancient traditions.

The result was a century of intellectual ferment that was a world removed from the eighteenth century, when intellectual activity was limited to small numbers of learned pandits who produced abstruse and largely unoriginal commentaries on ancient Sanskrit texts. In the nineteenth century those intellectuals who discussed religious topics were familiar with other world religions, addressed the growing reading public by writing in vernacular languages, and organized dozens of regional and national societies to discuss and promote their views. There also emerged a large class of university-educated Hindus and smaller numbers of Muslims who were fluent in English and well versed in Western history and literature. Not all of these individuals were “intellectuals” who wrote books and articles and engaged in public debate. But they made up an audience for such writers, who addressed a wide range of issues that included by the end of the century the timing and circumstances of Indian independence.

China’s intellectual history was unique in that its scholars and philosophers were also the empire’s administrators and the key advisers to the emperor. This had been the case ever since the seventh century CE, when the civil service examination system was established. By the Qing era, China’s educational system was geared to preparing young men for the examinations, which tested their knowledge of writings attributed to Confucius and some of his early followers and a small number of approved commentaries.

The eighteenth and early nineteenth centuries were a glorious period in Chinese scholarship, one that produced lively exchanges among different schools of Confucianism and important research in the fields of linguistics, calligraphy, mathematics, astronomy, and geography. But the

scholar-officials who ran the government and advised the emperor were slow to react to the Western threat to China and for the most part resisted changes in the country's intellectual culture or system of government. Well into the nineteenth century the prevailing attitude, even among the reform-minded, was that little could be learned from Westerners except a few mechanical skills. The scholar-officials showed little interest in foreign travel or the subject matter taught in missionary schools. Many viewed missionaries as rivals and sought to stir up opposition against them. Only after military defeats by the Western powers in the Opium War (1839–1842) and the Arrow War (1856–1860) and the eruption of major rebellions across the empire in the 1850s did a small number of scholar-officials embrace a movement of self-strengthening by promoting the study of foreign languages, Western science, and mathematics and learning Western military technology. And only after another stinging military defeat in the Sino-Japanese War (1894–1895) and the imposition of another harsh treaty after the suppression of the Boxer Rebellion (1898–1901) did conservatives at the imperial court concede that drastic action was necessary.

By the end of the nineteenth century, despite official indifference, new ideas from the outside world gradually began to influence many Chinese, especially those living in the treaty ports. Sizable numbers took advantage of educational opportunities provided by the missionaries. Others were introduced to Western history and literature by the availability of translations into Chinese. Still others corresponded with family members and friends who were part of the expanding numbers of overseas Chinese. After 1895 tens of thousands of young Chinese studied in Japan, where they could see firsthand how another Asian nation had reversed its fortunes by radically breaking with its past. Small numbers of Chinese became ardent democrats and nationalists and formed revolutionary organizations dedicated to overthrowing the Qing. Organized into the Revolutionary Alliance by the Christian, Hawaii-educated Sun Yatsen in 1905, these groups prepared the ground for the overthrow of the Qing in the Revolution of 1911.

As in China, Confucianism dominated intellectual life in Tokugawa Japan. Confucianism

was supported by the shoguns and taught in Japan's many private and state-supported academies. Confucian scholars, drawn mainly from the samurai class, wrote histories, analyzed texts, and entered into many of the same debates that were exercising the minds of Confucianists in China. Confucianism in Japan, however, did not enjoy an intellectual monopoly. In the 1700s advocates of "Dutch Learning" learned Dutch so they could read European texts, especially on medicine, science, and mathematics. Other scholars connected with the National Learning Movement rejected Chinese influence and Confucianism altogether and looked to Shintoism and Japan's ancient imperial past as the source of Japan's unique strengths and virtues.

All of these groups took part in the debates of the first half of the nineteenth century, when Japan faced increasing foreign pressures and mounting social tensions. Many Japanese advocated a continuation of Japan's policy of isolation and backing it up by political unification and military reform. Others advocated opening Japan to Western ideas, technologies, and even trade. Still others embraced a Japanese version of self-strengthening, represented in the thought of Sakuma Shozan, who coined the phrase "Eastern ethics and Western science." These debates reached a fever pitch in the years following the "opening" of Japan by Commodore Matthew Perry in 1853 and then subsided with the Meiji Restoration of 1867–1868.

After the overthrow of the shogunate, Japan's new leaders revealed themselves as supreme pragmatists, supporting whatever doctrine or policy would make Japan a stronger and more united state. In the 1870s, for example, in the hope of strengthening reverence for the emperor and devotion to Japan's unique religious heritage, the government sponsored a revival of Shintoism. This policy was quietly abandoned by the early 1880s, but the more important policy of "seeking knowledge throughout the world" was not. In the 1870s the government sponsored foreign studies for young men, imported hundreds of Westerners to fill administrative positions and teaching jobs, and encouraged the translation of Western books into Japanese. The government's most important contribution to Japanese thought was its encouragement of

education. By 1905, 95 percent of all children of statutory school age were in school. This increased demand for newspapers, journals, magazines, and books in which Japan's thinkers were able to discuss politics, foreign relations, women's rights, and a host of other issues facing the new Japan.

—James H. Overfield

The Brahmo Samaj Movement

The Brahmo Samaj (Society of Worshipers of One God) was founded in 1828 by Raja Rammohun Roy in Calcutta, India. It began as an attempt at religious and social reconstruction in response to the challenges posed by Christian missionary work and the Western ideas that entered India in the wake of British colonialism. As part of the Bengal renaissance, the movement aimed to reform Hinduism, purging it of its idolatry, caste system, and other features deemed to be debasing while preserving its higher elements of truth, spirituality, and essential religion. The Brahmo Samaj stands firmly on theism, the worship of a single omniscient and omnipotent God. Although distinctly Hindu in its origins, the Brahmo Samaj adopted concepts from other religions, especially Unitarianism that affirmed the existence of One God, applying reason in religion and working out one's salvation with diligence. The Brahmo Samaj believes that all truth is of God and respects the prophets of all religions. Raja Rammohun Roy (1772–1833), Debendranath Tagore (1817–1905), Keshub Chunder Sen (1838–1884), and Sivanath Sastri (1847–1919) were key figures in shaping the Brahmo Samaj.

Rammohun Roy, born into an orthodox Brahmin family in the eastern state of Bengal, became multilingual, learning Sanskrit, Arabic, Persian, and English. He also acquired an intimate knowledge of Hinduism, Islam, and Buddhism, developing a zeal for religious reform derived partly from Hindu and Muslim thought and later from Unitarian ideas. He rejected worship of religious images as indicative of prejudice and superstition and contrary to common sense. He also rejected the practice of sati, which was perpetrated in the name of religion and involved the burning of widows on their husbands' funeral pyres. Roy and his followers formed the Brahmo Sabha

(later Brahmo Samaj) to reform society through promoting these ideals. They met regularly for religious services during which passages from the Upanishads were read, sermons were delivered, and hymns were sung. After Roy's death the Brahmo Samaj went into decline.

In 1838 Debendranath Tagore, father of the famous Indian poet Rabindranath Tagore, revived and reorganized the Samaj. However, Tagore did not share Roy's cosmopolitan vision and opposed Christian missions. Tagore staunchly believed in the infallibility of the Hindu scriptures and developed the Samaj in accordance with his beliefs. Under his guidance and leadership the Samaj became an active Hindu missionary organization, drawing adherents from among educated Hindus and establishing branches in several towns in Bengal and other Indian states.

Keshub Chunder Sen was the third major figure to impact the Samaj, albeit in a mixed

Rammohun Roy was a leading social and religious reformer of early-nineteenth-century India and has been called the father of modern India. (R. N. Samaddar, Raja Ram Mohun Roy, 1911)

➤ KUCH BEHAR CONTROVERSY, 1878

In 1878 a new crisis arose in the Brahmo Samaj when Keshub Chunder Sen announced the marriage of his underage daughter to the youthful Maharaja of Kuch Behar. Many of his followers criticized him for his decision because they believed that the marriage was in violation of the Indian Marriage Act of 1872, which banned child marriage; that Keshub had arranged the marriage to gain material benefits and social status; and that the marriage would feature idolatrous ceremonies that went against Brahmo principles. When Keshub justified his decision on the basis of divine revelation and proceeded with the marriage, many of his erstwhile followers, led by Sivanath Sastri, withdrew from the Brahmo Samaj of India to form the Sadharan Brahmo Samaj. Keshub continued as the leader of the Brahmo Samaj of India, which in 1880 became the Navavidhan Samaj, or Church of the New Dispensation.

—Abhi Janamanchi

manner, leading ultimately to its fragmentation into three factions. Sen rejected the caste system and child marriage and promoted women's education and the remarriage of widows. Drawing on world scriptures, he gave the Samaj a universal character. However, by 1865 differences between him and other members of the Brahmo Samaj became sufficiently acute that he split off from the parent group and formed the Brahmo Samaj of India. A further schism resulted from the marriage of his underage daughter to the maharaja of Kuch Behar. Sen's claims that the marriage was in accordance with God's will disenchanted some of his associates, who in 1878 responded by founding the Sadaran Brahmo Samaj. Sen continued as leader of the Brahmo Samaj of India, and in 1881 his group adopted the name the Navavidhan Samaj, or Church of the New Dispensation.

Sivanath Sastri became one of the prime movers of the Sadaran Brahmo Samaj, the largest Brahmo group in existence today. While maintaining traditional Brahmo characteristics of faith in a personal God, congregational worship, and condemnation of idol worship, the Sadaran Samaj also emphasized universal brotherhood,

opposed caste distinctions, and promoted a well-ordered organization.

Today the Brahmo Samaj is a very small minority with a mostly hereditary membership. Although unable to purge Hinduism of what it saw as idolatry and superstition, it did provide a rational critique of religious thought and practice that contributed to the establishment of a secular, democratic Indian society.

Nineteenth-Century Hindu Reformers

Both Christian missionary educators such as William Carey (1761–1834) and Alexander Duff (1806–1878) and secular Orientalist scholars such as John Muir (1810–1882) and Max Muller (1823–1900) helped arouse the reforming spirit within Hinduism in India. In the case of the Christian missionaries, they did so through their promotion of a combined package of Christianity and Western education. Orientalist scholars aroused the reforming spirit through their promotion of Hindu traditions and texts that were translated and made available for the first time in their history to the broader general public in both India and around the world.

First among the Hindu reformers was Ram-mohun Roy (1772–1833), a religious teacher from the Brahmin caste who was regarded as "the father of modern India" even though his

► WORLD HISTORICAL CONTEXT OF NINETEENTH-CENTURY HINDU REFORMERS

Nineteenth-century Hindu reformers must be understood within their broader world historical context. Similar religious, cultural, and national reform movements were taking place all across Asia in response to Western imperialism. Muslims in the Ottoman empire were spearheading various overlapping reform movements, including Pan-Islamism, Pan-Arabism, and Arab nationalist reforms, which both cooperated with and competed against Turkic nationalist reform efforts. These two main Ottoman groups, the Arab and Turkish Muslims, in turn influenced the Turkic Muslims of the Russian empire in their Jadidist (New Method) reform movement, which emphasized both Pan-Islamic and Pan-Turkic ideas within the Russian political context. Among the Japanese the Meiji Restoration (1868–1912) was under way, with participation by state-supported Shinto priests, among others. And China too, with its Confucian tradition, was experiencing its first stirrings of anti-Western Chinese nationalism.

In all these contexts of Asian-Western contact and exchange, the basic underlying question was the same: How should the Asian traditions respond to the Western challenge and, with it, Western influence upon their historic cultures? In general, three main responses were developed: wholesale rejection of “foreign” Western influence with a reversion to “pure” Asian ways, an attempted synthesis between Asian and Western ways, and the admiration and acceptance of Western “superiority” and, with it, adoption of predominantly Western ways in place of former Asian ones. All three of these tendencies are evident among nineteenth-century Hindu reformers. In both the second and third cases, the response sometimes involved conversion to Christianity as the Western religion. More often than not, however, it meant reform of the Asian religious tradition borrowing from Western Christianity as a model, which might include incorporation of Christian ideas and practices into the Asian religious tradition.

—*R. Charles Weller*

movement is considered to have originally been more Bengali than Indian. Roy founded a society named the Brahmo Sabha in 1828 to help facilitate his reform efforts. In 1841 it was renamed the Brahmo Samaj under his successor. Roy was educated in classical Hinduism, Islam, and Christianity, with working knowledge of Sanskrit and Persian as well as biblical Hebrew and Greek. He followed a comparative religious approach that sought to draw from all major world religious traditions subsumed under a reformed universalist Hinduism grounded in human reason and morality. This is reflected in the English name of his group, Fellowship of Believers in the One True God. Additionally, like his contemporary the Christian missionary William Carey, Roy was active in socioreligious reform, including opposition to the Hindu tradition of sati, the burning alive of widows of certain castes with their husbands upon their death. Debendranath Tagore (1817–1905), who created Brahmo Samaj in 1843 by merging his Tattwabodhini Sabha with Roy's Brahmo Sabha, was Roy's spiritual successor. Brahmo Samaj had spread into all corners of India

by the turn of the century. A sectarian offshoot of Roy's group was started by Keshub Chunder Sen (1838–1884). It drew heavily on Judeo-Christian language, imagery, and ritual, including baptism, communion, and a Trinitarian conception of God resulting in a Hindu-Christian synthesis.

Some 50 years later, in 1875, another Brahmin teacher, Swami Dayananda Saraswati (1824–1883), emerged to establish the Arya Samaj society in Bombay and Lahore. In some respects Arya Samaj may be viewed as a conservative reaction to the Brahmo Samaj. Dayananda rejected Western influence as well as both Christianity and Islam as impure foreign threats that aimed to undermine Hinduism. He insisted that among the Hindu scriptures only the four Vedas held infallible authority. He sought to transcend caste and nationality, offering equal access to all within the Hindu vision he espoused. In spite of his rejection of Western ideals and values, some have seen traces of Western and Christian missionary influence in his socioreligious activism. He strongly opposed Hindu-Indian customs such as child marriage, the idea of being “untouchable,”

and the subjugation of women, among other customs. On the latter point Dayananda was, for his time, a pioneer in his granting of full rights of membership and participation to women within his society. The Arya Samaj has had a long, deep impact upon Hindu and Indian society down to the present day, particularly through its high schools and colleges, leaving likewise its mark upon Indian politics, especially via members of the Bharatiya Janata Party.

A third significant Hindu reform movement was the Ramakrishna Mission named after Sri Ramakrishna Paramahansa (1834–1886), who also was a Bengali. His approach can be called mystical and ecumenical, based in meditation and trance experiences drawing primarily from tantric and bhakti Hindu traditions. In this respect, his movement can be compared with other mystical devotion-oriented movements in world religious history. The life and teaching of Ramakrishna came to the world's attention through his closest and best-known disciple, Narendranath Datta, better known as Swami Vivekenanda (1863–1902). Vivekenanda not only spread Ramakrishna's message throughout India, but he also successfully represented Hinduism at the 1893 World Parliament of World Religions in Chicago, engaging also in lecture tours across North America and Europe. Perhaps in part as a response to Christian missionary efforts in South Asia, the Ramakrishna Mission came to represent its vision of Hinduism as the hope of humanity, the vehicle for the salvation of the world, believing it to be the purest and most accurate expression of belief and devotion among the world's religions.

The two leading figures of Hindu reform who followed these pioneers were Rabindranath Tagore (1861–1941)—who is not to be confused with Debendranath Tagore mentioned above in connection with the Brahmo Samaj—and Mahatma Gandhi (1869–1948). But the core of their legacy lies within the early twentieth century, serving as a point of closure for the discussion of nineteenth-century Hindu reformers, with all of them contributing not only to religious but also to social and national reform in India and broader South Asia in response to the challenge of Western expansionism.

Kang Yuwei and the New Text Movement in China

Kang Yuwei (1858–1927) was a brilliant and highly influential reformist thinker in the last two decades of the Qing dynasty (1644–1911) and an advocate of imperial restoration in the period after the fall of the Qing. An ardent student of Confucianism, raised in a family of scholar-officials, in his struggle to pass the civil service examinations he took up Buddhist meditation as a form of relaxation to balance and deepen his studies. A period of contemplative retreat in 1878 led to an enlightenment experience in which he perceived the unity of his self with Heaven, Earth, and all things and saw himself as a sage destined to “set in order all under Heaven.”

After attending the metropolitan examinations in Beijing in 1882, on his return he passed by Shanghai, where he was impressed by the cleanliness and orderliness of the foreign concessions. He also purchased books about Western political institutions and natural science. He became determined to lead the reform of China's institutions, and by 1888 he was memorializing Emperor Guangxu about the national crisis and the need for a thorough reform of government and the institutional system.

In 1891, back in his native Guangdong, he founded an academy where he began to teach promising young students and develop the theory necessary to carry out his reform. His most important theoretical work, *Datong shu* (The Book of the Great Unity), begun in 1894, listed the many forms of human suffering and described an ideal socialist society and classless

world order wherein all these problems would be solved. Though his vision of the abolishment of property and of the traditional family system to be replaced by government nurseries and schools and by equality and freedom between men and women was idealistic in the extreme, it was accompanied by a progressive concept of three stages of human civilization in which the highest ideals would be realized only in the final stage. Unlike most Chinese scholars of his time, Kang recognized that science and technology were essential for advancing the welfare of mankind, though he had no use for capitalism.

In April 1895 Kang was in Beijing along with examination candidates from every province, all of whom were indignant when they heard about the cession of Chinese sovereignty required by the treaty of Shimonoseki that the Qing government was about to sign with Japan after China's defeat. Kang spent several nights drafting a long memorial to the emperor, after which he called a meeting of 1300 candidates to get their support for the petition, which demanded that the Qing government reject the treaty, move the capital, and initiate a major program of reform that would turn it into a constitutional monarchy dedicated to promoting commerce and industry. Kang organized a study society dedicated to investigating how to make the country strong. His memorials continued, and in spite of increasing opposition from conservatives, his efforts deeply moved Emperor Guangxu, who eventually agreed to undertake the "Hundred Days of Reform" in 1898. Unfortunately, real power was in the hands of the Empress Dowager Cixi, who in league with the conservative factions in the government soon moved to crush the reform movement and execute those of its leaders who were unable to escape (six were executed). Kang managed to flee to Hong Kong and then went into exile in Japan with his famous student Liang Qichao, later travelling to many countries where he worked to rally support for his vision of reform among overseas Chinese in competition with Sun Yatsen's revolutionary faction.

The indigenous ideas that Kang used as the basis of his reform program were taken from the "New Text" school of Confucianism that had been the ideological basis of government in the Later Han dynasty (25–220 CE), in competition

➤ CONFUCIUS AND THE DOCTRINE OF PROGRESS

In the following passage, from Kang Yuwei's commentary on the Analects of Confucius, Kang draws on Confucius to support his theory of human progress.

"Confucius was the founder of a doctrine. He was a godlike sage king. He complements Heaven and earth and nurtures the myriad things. All men, things, and principles are embraced in the Great Way of Confucius. He is, therefore, the most accomplished and perfect sage in the history of mankind. . . . The Way of Confucius embraces the evolution of the Three Sequences and the Three Ages. . . . The eras of Xia, Shang, and Zhou represent the succession of the Three Sequences, each with its modifications and accretions. By observing the changes in these three eras one can know the changes in a hundred generations to come. For as customs are handed down among the people, later kings cannot but follow the practices of the preceding dynasty; yet, since defects develop and have to be removed, each new dynasty must make modifications and additions to create a new system. . . . There will be a day when everything throughout the earth, large or small, far or near, will be like one. There will no longer be any nations, no more racial distinctions, and customs will be everywhere the same. With this uniformity will come the Age of Great Peace. Confucius knew this in advance."

with the "Ancient Text" school whose texts became the basis of the later schools of Confucianism of the Sui-Tang period and the Song, Yuan and Ming dynasties. By returning to the interpretations and world-view of the New Text school (whose texts were actually older and more authentic than those of the "Ancient Text" school, many of which Kang argued had been forged during the short Xin dynasty from 9–24 CE),

Kang found a sophisticated ideological weapon he could use to gain the support of Confucian-educated officials and counter the arguments of conservatives. For the New Text school had a vision of Confucius as the founder of a religion and as a great reformer who had actually authored the Confucian classics, claiming their ancient provenance only to gain authority for his actually very new teachings. New Text Confucianism emphasized cosmic forces not only in history but in all aspects of life, regarding Heaven as a consciously acting power watchful over human affairs. “Adjustment to circumstances” was one of the keystones of the New Text philosophy, referring to an act contrary to the normal standards of conduct or to the constants of life but ultimately for the good. As scholar Jack Dull noted, “The New Text scholar official had a certain amount of freedom of action in any given situation, but the Old Text philosophy taught that in all circumstances the official had only one route to follow: loyalty and subordination to the ruler. . . . In place of the emperor to whom the official owed complete loyalty, the New Text scholar-officials felt that they were ultimately answerable to the God on High [*Shangdi*] or to Heaven. . . . Their world was one in which the ultimate source of power was not the throne but Heaven; they lived in a divine world whereas the Old Text scholars lived in one that was eminently human and governed by man’s history.” Here we are presented with an image of Confucius and Confucianism drastically different from the one that has come down to us—and the one that constituted the ideology of the old system, but it was just what Kang needed if he was going to radically reconstruct China’s political system to fit the world of the twentieth century.

Confucian Scholars Confront the West—Kang Yuwei and Liang Qichao

Seeking to synthesize Confucianism with new ideas from the West, Kang Yuwei (1858–1927) has been called by many the last great Confucian theorist, including by his greatest student, Liang Qichao (1873–1929). Both men saw the need to allow Western learning to revive Confucianism through reform. The lives of these two great Confucian thinkers and political activists can be divided by the dramatic events of the One Hundred Days Reform of 1898, when they had direct access to the emperor and effected rapid changes at the highest levels of government before a conservative palace coup reversed the reforms. Escaping execution, both Kang and Liang fled to exile in Japan and then to overseas Chinese communities of Hawaii, Canada, the United States, Europe, and Southeast Asia, and for over a decade they lived in exile honing their use of Western-inspired tools of nationalism. While both men were prolific writers of serious, if controversial, Confucian scholarship, their most important work was arguably appropriating from the West modern mass journalism to disseminate new ideas of constitutional governance, science, and nationalism beginning in 1895. Some historians have focused on the thought of Kang and Liang and others on their involvement in the reform movement. Both must be understood together.

In 1888 Kang Yuwei, still a commoner unsuccessful in the highest level of bureaucratic exams, attempted to memorialize the emperor to encourage reform. Discouraged by his failure, Kang turned to scholarship and in 1891 published a book challenging the authenticity of some of the most important "old texts" of the Confucian canon, borrowing another scholar's thesis without acknowledging it. The book was criticized by his peers and banned by imperial decree several years later. At this time Kang met Liang Qichao, his junior in years but more advanced in the official degree system. Liang nonetheless became Kang's pupil and helped Kang set up a school that mixed preparation for the official exams with study of Western science and military drill. With the help of Liang and other students, in 1897 Kang published a book in which he claimed that Confucius was a reformer, misrepresented by centuries of conservatives.

Repeated Qing defeats at the hands of European and Japanese imperialists motivated Kang and Liang to devote their lives to writing and political action urging reform. The German seizure of the Qingdao region of Shandong in 1897 and other incursions further impelled Kang and Liang to action. In 1898 Kang's memorials started getting through to the emperor, and reforms were issued from Beijing in rapid succession. Conservative elements, led by the emperor's aunt, Dowager Empress Cixi, imprisoned the emperor and reversed the reforms, while Kang and Liang fled separately to Japan. Impressed by the success of Japan's own Meiji Reforms, Kang and Liang redoubled their efforts by continuing to publish periodicals in the treaty ports of China. Kang indignantly refused offers from the Western-educated revolutionary Sun Yat-sen to cooperate, but Liang flirted Sun's concepts of republicanism and revolution. Liang returned firmly to Kang's constitutional monarchy camp before the 1911 Revolution. After the revolution eliminated the Qing monarchy, Liang's star rose while Kang's fell. Liang returned to China to take various political positions in the quick succession of governments, at first supporting president Yuan Shikai and then fighting Yuan's 1915 attempt to make himself emperor. By the end of World War I (1918) Liang again traveled

the world and realized the inherent weaknesses of materialistic Western civilization that had led to the war's slaughter and destruction. His writings during the last decade of his life reflected disillusionment with Western culture and science, with the political situation in China, and even with his former teacher Kang Yuwei's excesses of scholarship. Both men, but especially Liang, left a strong imprint on Chinese journalism, government, education, language reform, and historiography.

The End of Official Confucianism

The political role of Confucian academies in China diminished in the early Qing period. Manchu emperors, aware of the role of the academies in the fall of the Ming dynasty, suppressed the political activism of academies such as the Donglin Academy, which had been revived in 1604 by scholars and officials to protest the many shortcomings of public life under Ming rule. The Confucian academies did retain control of the educational system and the rigid written examinations through which scholars attained civil service positions in the imperial bureaucracy. Passing the highest-level *jinsbi* examination was the ultimate goal of years of study. Scholar officials from a rural gentry class of literati elites populated the Qing government at every level.

However, by the late nineteenth century the examinations were providing far more degree holders than there were available government positions. As a result, traditional advancement

THE IMPERIAL EXAMINATIONS

The Imperial Examinations trace back to the Han dynasty (206 BCE–220 CE). In theory the examinations gave everyone in the empire, regardless of social status, the opportunity to become an official in the government. Due to the expense involved in preparation for the exams, most graduates came from a privileged gentry background. There were three levels: *shengyuan*, offered annually; *juren*, offered at the provincial level every three years; and *jinshi*, offered in the imperial capital every three years. The examinees were identified by number, not by name, and the examinations lasted between 24 and 72 hours. The exams were abolished in 1905.

—John Harney

in the civil service was blocked for many classically trained scholars. This issue was exacerbated by defeats at the hands of Western powers beginning with the Opium War (1839–1842) and the shock of the Taiping Rebellion (1851–1864). The psychological impact of the West's demonstrable technological dominance was immense. Western intellectual achievements also created a challenge for the basic principles of the Neo-Confucian order of the Qing state. The self-strengthening movement, originating in the 1860s, was an early attempt to adapt Western advances to a Chinese intellectual base, but the movement was scattered and uncoordinated.

In the late 1880s and early 1890s Kang Yuwei (1858–1927), an ambitious scholar from Guangzhou, began to agitate for reform. Kang, like many of his compatriots, felt humiliated at Chinese obeisance to foreign powers. He believed that radical reform could revitalize China. Kang and his one-time student Liang Qichao (1879–1923) saw Meiji Japan as an example for Chinese modernization; Japan was an Asian country that had successfully adapted Western ideals to modernize the state. Modernization itself was a new concept, derived from Western influence and the Enlightenment ideal of a progressive form of history, based on the acceptance that a linear path existed between an unsophisticated past and an improved future. This was at odds with the cyclical analysis of

history prevalent in imperial China and in Confucian circles. Kang and Liang argued that the periodization of history along progressive lines could be justified in Confucian terms. This was a direct challenge to reforming Chinese intellectual thought.

Kang and Liang were both interested in reforming state education, still dominated by Confucian academies and grueling written examinations. The 1898 Hundred Days Reform, in which Kang has long been considered a central figure, abolished the eight-legged essays, so long a fixture in the written examinations. The education system was not reformed further, typical of the limited immediate effects of the Hundred Days. By 1901, however, the conservative officials responsible for stifling the Hundred Days Reform had accepted reform as inevitable. The Qing government's New Policies set up a hierarchy of modern schools throughout China based on a Japanese model alongside the classical examination system. The two systems proved incompatible, and in 1905 the classical examinations were abolished, rendering obsolete the Neo-Confucian gentry elite who had provided the backbone of the old system.

—John Harney

Japanese Influence on China, 1890s–1914

The centuries of relations between Japan and China had been largely beneficial to both states, but the Sino-Japanese relationship underwent a fundamental change for the worse in the late nineteenth and early twentieth centuries. As China crumbled under the weight of age and opium, Japan flexed its new reformist muscle and began to bring portions of China into its

imperial orbit. During 1894–1895, sparked by rivalries in Korea, Japan attacked China, gaining victory in the Sino-Japanese (or Jiawu) War, a conflict that resulted in Japanese control of Taiwan for the next 50 years.

Japan was nevertheless a magnet to Chinese intellectuals and reformers from the 1890s to 1914. Japan's attractions were deeply tied to domestic developments in China, where the Qing dynasty held a death grip on reform. Chinese reformers, frustrated with Qing immobility, saw in Japan a model for Asian modernization. The unbending traditionalism of the Qing court in Beijing, headed by the old Manchu empress dowager, was unmoved by Japan's rapid ascent since 1868. The Qing alienated students and intellectuals, rendering Japan's economic buoyancy and Western technology all the more fascinating. During the closing years of the Qing era and the warlord period that followed, thousands of Chinese students traveled to Japan, by far the most popular destination for overseas Chinese students. The writer and reformer Lu Xun (1881–1936) and the poet Guo Morou (1892–1978) each spent significant time in Japan, as did the future Chinese communist diplomat Zhou Enlai (1898–1976). Before Japan repelled these men through glorification of empire in the 1930s, each of them responded to Japan with poetry and nostalgia.

Not only Chinese intellectuals, artists, and future statesmen flocked to Japan; so too did revolutionaries seeking to overturn the Manchu dynasty. Sun Yatsen (1866–1925), the founder of the Chinese Nationalist Party (Guomindang), was one such revolutionary. Sun was an admirer of Japan, and his years in Tokyo stimulated dreams of a Pan-Asian modernity enabled by intense Sino-Japanese cooperation.

The growth of Japanese influence and its appeal for Chinese revolutionaries such as Sun Yatsen was matched and eventually overcome by apprehension toward Japan due to its attacks on Chinese soil. Having laid out a “periphery of advantage” that ran squarely through Manchuria, the Japanese increased their economic privileges in Chinese port cities and expanded control along the trunks of the Manchurian railways. These privileges increased and Japanese modernization of portions of Manchuria and the Chinese mainland accelerated after Japanese

YAMAGATA ARITOMA'S VIEWS OF SINO-JAPANESE RELATIONS

On the eve of World War I the distinguished Meiji statesman and military leader expressed these views concerning cooperation between China and Japan.

“The principal aim of our plan should be to improve Sino-Japanese relations and to instill in China a sense of abiding trust in us. . . . If the colored races of the orient hope to compete with the so-called culturally advanced white races and maintain friendly relations with them while retaining their own cultural identity and independence then China and Japan, which are culturally and racially alike, must become friendly and promote each other's interests. . . . If we fail to dissipate China's suspicion of us, she will rapidly turn against us and turn more and more to America. Our politicians must be sternly warned against raising the issue of radicalism . . . it would be more prudent not to raise the issue of a league of colored people. . . . China must be won over by hints and suggestions . . . before we can realize our plans.”

Yamagata Aritoma, quoted in Marius B. Jansen, *Japan and China: From War to Peace, 1894–1972* (Chicago: Rand McNally College Publishing, 1975), 202.

victory in the Russo-Japanese War (1904–1905). For China, Japan was a fierce and often dominant rival for regional influence in Northeast Asia. Participation in the bloody eight-power response to the Boxer Rebellion (1899–1901) enhanced Japanese global prestige but confirmed suspicions among the Chinese that in spite of its Pan-Asian rhetoric, Japan was but a predatory power in the European mold.

The destruction of the Qing dynasty in 1911 opened the door to increased Japanese influence in China. The outbreak of World War I in August 1914 brought new Japanese assertiveness in China. In particular, the seizure of the German base at Qingdao aggravated Chinese nationalistic sensibilities. The Okuma government's “21

Demands” of China, accepted by warlord Yuan Shikai’s government in Beijing, were the most notorious example of Japan’s disdain for China. The pragmatic Japanese attitude toward the mainland, including financial and military relationships with local Chinese warlords, soured the views of more Chinese toward Japan. On May 4, 1919, the full-scale anti-Japanese demonstrations erupted in Beijing, portending both China’s proud refusal to submit to Japanese imperatives and the sanguine holocaust of the second Sino-Japanese War.

Dutch Learning in Japan

“Dutch Learning” is the term for European knowledge brought to Japan by Dutch traders and propagated by samurai scholars during the Edo period (1600–1868). The dissemination of Dutch Learning, or *rangaku*, was the primary means by which Japanese scholars and political officials stayed abreast of world events during Japan’s long period isolation, or *sakoku*.

Merchants from the Netherlands began trading with Japan in 1609. Because the Protestant Dutch were more interested in commerce than in missionary activity and were openly hostile to their Portuguese and Spanish rivals, Japan’s anti-Catholic Tokugawa rulers were generally tolerant of their presence. When shoguns Hidetada (r. 1605–1623) and Iemitsu (r. 1623–1651) began expelling European missionaries and merchants from Japan in the 1620s, only the Dutch were

allowed to remain. They were confined, however, to a small facility on the man-made island of Dejima in Nagasaki Bay, and only one Dutch ship per year was permitted to offload its cargo.

Besides distributing silks, spices, porcelains, and other European and Asian goods, the Dutch trading post was a rich source of European knowledge in art, medicine, mathematics, astronomy, shipbuilding, and economics. The Tokugawa allowed a restricted number of scholars to study Dutch for the purpose of communicating with the foreign traders and for studying their books. The trade agreement with the Netherlands also required the captain-general of the Dutch East India Company to appear before the shogun each year and present a formal briefing of world news, with rangaku scholars serving as interpreters at these audiences.

While the content of Dutch Learning often differed from the orthodox teachings of Tokugawa Neo-Confucianism and was considered dangerous by many traditionalists, the expansion of European knowledge between the seventeenth and nineteenth centuries attracted the attention of scholars such as Honda Toshiaki (1744–1821) and Kaiho Sieryo (1755–1817). In the late eighteenth century as corruption and inefficiency took their toll on the Tokugawa political economy, these and other rangaku scholars used Dutch Learning to criticize the Edo regime. Observing that several European nations had surpassed Japan in wealth and power and posed a growing military threat, rangaku scholars urged the government to embrace European technologies, if only for the purpose of achieving material and military parity. Progressive scholars such as Maeno Ryotaku (1723–1803) publicly speculated that European civilization might be superior to Japan’s, and criticisms of the centuries-old isolation policy became prominent in national debates.

In the early 1800s Russian, British, and American vessels began to appear in Japan’s coastal waters, and their captains grew increasingly persistent in their demands for access to Japanese ports. In 1844 King William II of the Netherlands warned Shogun Ieyoshi (r. 1837–1853) that if Japan continued to refuse requests for trade, it would likely suffer the fate of Qing China, recently humiliated in the Opium War.

➤ HONDA TOSHIAKI—A SECRET PLAN FOR GOVERNMENT, 1798

In the late eighteenth century Honda Toshiaki and other *rangaku* scholars championed Dutch Learning (European knowledge brought to Japan by Dutch traders) to criticize the Edo regime. Criticism of the centuries-old isolation policy became prominent in national debates. The following is an excerpt from Honda Toshiaki's *A Secret Plan for Government*.

"There is no place in the world to compare with Europe. It may be wondered how this supremacy was achieved. In the first place . . . they have delved deep into the beauties of the arts, and have divined the foundations of government, and have

established a system based on a thorough examination of the factors that make a nation prosperous. Because of their proficiency in mathematics, they have excelled also in astronomy, calendar making, and surveying. They have elaborated the laws of navigation such that there is nothing simpler for them than to sail the oceans of the world."

The question of realm defense took on new urgency, and Dutch Learning offered revised military tactics and provided the technology that allowed new fortifications, munitions, and shipyards to be built in Japan. Pragmatic activists such as Sakuma Shozan (1811–1864) called for a synthesis of "eastern ethics and western science" as a means of building material strength while preserving Confucian values, but time ran out on the possibility of using Western learning to hold Western powers at bay. In 1854 U.S. Navy commodore Matthew C. Perry's flotilla of "black ships" forcibly opened Japan to Western trade. In the following decades, traditional Dutch Learning yielded to an explosion of cultural, scientific, and technological exchange with the West.

The National Learning Movement

The National Learning Movement, or Nativist Learning, was a school of Japanese thought during the Edo period (1603–1868) that looked to

ancient mythology, poetry, and religion for the essential core of the Japanese spirit. By asserting the unique qualities of native tradition found in classical literature and the Shinto religion, scholars of National Learning, or *kokugaku*, helped shape an emerging Japanese national identity. While the movement has been traced to early Tokugawa court scholars who tried to separate the founding of their regime from Chinese historical tradition after the collapse of the Ming dynasty (1368–1644), National Learning evolved into a complex and even revolutionary expression of Japanese protonationalism.

Kokugaku took shape in the early eighteenth century when nativist intellectuals sought to define a spiritual identity that transcended such "foreign" philosophical constructs as Neo-Confucianism, the official ideology of the Tokugawa regime, and Buddhism, which for centuries had been the popular religion of Japan. Scholars such as Kado Azumamaro (1669–1736) and Kamo Mabuchi (1697–1769) sought to assert the superiority of Japanese culture by elevating Shinto over Buddhism and reviving awareness of Japan's rich heritage of stories, songs, and mythologies. Perhaps the most influential proponent of National Learning was Motoori Norinaga (1730–1801), a merchant scholar whose commentaries on the *Manyōshū* anthology (759 CE) and the *Tale of Genji* romance (1000 CE) described these texts as embodiments of an ideal native spirit. Norinaga's massive study on the

➤ KAMO MABUCHI, FROM *A STUDY OF THE IDEA OF THE NATION*

“In ancient days, Japan was governed in accordance with the natural laws of Heaven and earth. There was never indulgence in such petty rationalizing as marked China, but when suddenly these teachings were transmitted here from abroad, they quickly spread. . . . In Japan, generation after generation . . . had known prosperity, but no sooner were these Confucian teachings propagated here . . . than a great rebellion occurred. Later . . . the palace, dress, and ceremonies were Chinesified, and everything acquired a superficial elegance; under the surface, however, contentiousness and dishonesty became more prevalent.”

Kamo Mabuchi, “A Study of the Idea of a Nation,” in *Sources of Japanese History*, edited by David Jon Lu (New York: McGraw-Hill, 1974), 254.

myth-history *Kojiki* (Records of Ancient Matters) celebrated the archaic language of these chronicles as an aesthetic expression of the moral values that informed the Japanese soul.

In the late eighteenth century as Japan's economy began to stagnate and the samurai-led polity proved increasingly incapable of responding to social changes, dissatisfaction with the Tokugawa dynasty became widespread. National Learning, with its concern for the moral welfare of the Japanese people, became an intellectual bridge between the aspirations of ethical nationalists and the criticisms of Tokugawa detractors. With the work of Hirata Atsutane (1776–1843), kokugaku reached beyond the domain of literary studies and into the domains of religion and politics. Hirata's writings on Shinto appealed to both popular sentiment and nationalism, as they described the “way of the gods” as the unique relationship between the people in their day-to-day lives and a cosmic realm whose divine inhabitants favored the Japanese among the peoples of the earth. The revival of Shinto led to new articulations of the role of the emperor,

who was traditionally seen as both a direct descendant of the primordial gods and a living deity in his own right.

In the latter decades of the Edo period, scholars of the Mito School such as Tokugawa Nariaki, a member of the Tokugawa clan but a critic of the shogunate, argued that the emperor, not the shogun, ought to hold supreme power in Japan. These scholars cited the failures of the Tokugawa rulers to defend the realm against Western encroachment as evidence of the shogunate's inadequacy. As reform-minded scholars, disgruntled samurai, and angry peasants joined the chorus of *sonno joi* (“revere the emperor, expel the barbarian”), the discourses of kokugaku added philosophical weight to a political ideology that increasingly rejected the legitimacy of the Tokugawa shoguns and sought to restore power to the imperial throne.

While the Meiji Restoration of 1868 ultimately set Japan on the path toward modernization, several key elements of kokugaku thought were carried into the modern era and were even institutionalized in the Meiji Constitution of 1889. Among these were the doctrine of imperial divinity, the promotion of Shinto as a state religion, and the validation of native mythology as national history.

Late Tokugawa Confucianism

The dominant form of Confucianism during Japan's Tokugawa or Edo period (1603–1867 CE) was Neo-Confucianism, which developed in China during the Song dynasty (960–1279 CE) and dominated Confucianism in China during the Qing era (1644–1912). The followers of Neo-Confucianism combined aspects of Buddhism and Daoism with traditional (or Classical) Confucianism. Neo-Confucian scholars emphasized

moral cultivation, which made it appealing to Chinese emperors interested in the recruitment of government officials; by the end of the Song era, they gave Neo-Confucianism the status of orthodoxy, making mastery of its tenets essential for those preparing for the civil service examinations. Zen Buddhist monks, who traveled to China from Japan during this time, brought Neo-Confucianism with them on their return to Japan, where its study was limited to temples and monasteries. Beginning in the sixteenth century, Zen monks and priests introduced Neo-Confucianism to a wider audience, and it quickly became an important political ideology for samurai warlords.

An important scholarly family of the time, the Hayashi, the head of which was the former Zen monk Razan, eventually succeeded in having Neo-Confucianism elevated to the status of orthodoxy by the middle of the seventeenth century during the reigns of the third and fourth Tokugawa shoguns, Iemitsu and Ietsuna, respectively. The chief appeal of Neo-Confucianism for these shoguns was the emphasis on the benevolence and virtue of the ruler; thereafter, shoguns ruled for reasons of their values and character rather than their overwhelming military might. A key difference between Japan and China (as well as Korea and Vietnam), however, was the absence of civil service examinations in Tokugawa Japan. This meant that the Neo-Confucian orthodoxy did not have the same importance that it had in China, and scholars increasingly ignored it over the course of the eighteenth century. Many scholars turned to variant forms of Confucian learning such as Ancient Learning, a form of Confucian scholarship reminiscent of Classical Confucianism (i.e., pre-Neo-Confucianism). In addition, rival forms of scholarship such as Mito Learning, Dutch Learning, and National Learning developed. At the end of the eighteenth century, the head of the Tokugawa government, Matsudaira Sadanobu (1758–1829), a chief adviser and later a shogunal regent, sought to revive Neo-Confucian orthodoxy. Sadanobu viewed Neo-Confucianism as a way of preparing for government service able samurai warriors who would have the moral character to resist the lure of corruption. To this end, he revived the shogunal academy and

➤ “THE PROHIBITION OF HETERODOX STUDIES,” 1790

Matsudaira Sadanobu sent this document, known as the Kansei Edict, to the head of the Hayashi family requiring them to root out forms of Confucianism other than Neo-Confucianism from their school.

“[To the Hayashi family]: The teaching of Chu Hsi [(1130–1200), the chief systematizer of Neo-Confucian thought] has had the full confidence of successive shoguns since the Keicho era [1596–1615] . . . and your family generation after generation has been entrusted with the duty of upholding and expounding this teaching. It has been expected, therefore, that orthodox studies would be pursued without remiss and your students trained in accordance with it. Lately, however, various new theories have been put forward, heterodox teachings have become popular, and social standards have been broken down. Indeed, since it points to a complete decline in orthodox studies, this is a matter for the most profound regret and concern. Even among your own students, we have heard from time to time of those whose thinking is not pure and correct. . . . Not only in your own school, but in all others as well, you are advised to see to it that the orthodox doctrine alone is taught as the basis for the training of men for public service.”

Masudaira Sadanobu, “The Prohibition of Heterodox Studies,” in *Sources of Japanese Tradition*, Vol. 1, edited by Ryusaku Tsunoda et al. (New York: Columbia University Press, 1958), 493–494.

changed its curriculum back to an emphasis on Neo-Confucianism. These efforts were the centerpiece of his larger social and political agenda known as the Kansei Reforms. His efforts resulted in a resurgence of Neo-Confucianism, but the other forms of scholarship endured until the end of the Edo period.

The situation that Sadanobu inherited with regard to the status of Neo-Confucianism was as follows. At the shogunal academy in Edo, where the Hayashi family had established the

orthodoxy of Neo-Confucianism in 1640, the Neo-Confucian curriculum fell out of favor. It was replaced by a rival form of Confucianism, Ancient Learning, represented chiefly by Ito Jinsai (1627–1705) and Ogyu Sorai (1666–1728). Jinsai taught his students to develop a moral practice that resulted in real, ethical conduct rather than simply applying abstract norms gleaned from the Confucian classics to everyday life. The sources for his moral teachings were those same classical works, but his emphasis was on practice and not simply theory, which he believed characterized Neo-Confucianism. Sorai was skeptical of all moral teachings, believing that they had nothing to do with ordering society and bringing peace to the realm. Both Jinsai and Sorai were critical of the Neo-Confucian orthodoxy led by the Hayashi family, and their books found their way into the shogunal academy. For scholars who did not study in the shogunal academy, the appeal of non-Confucian forms of scholarship was strong during the eighteenth century. The three most important of these were Mito Learning, National Learning, and Dutch Learning. Mito Learning originated in the Mito domain, an important territory administered by one branch of the shogunal family, the Tokugawa. The scholars of Mito Learning did not completely reject Neo-Confucianism, as did Jinsai and Sorai. Instead, Mito scholars sought to blend Neo-Confucianism with the indigenous religion of Japan, Shinto. For this reason, they focused on classical Japanese literature and imperial histories—the scriptural sources for Shinto—in their attempt to domesticate Neo-Confucianism. The scholars of National Learning agreed with their Mito counterparts on the importance of Shinto but de-emphasized Neo-Confucianism. They sought to define and articulate a unique Japanese cultural identity, and in this effort they focused on the classical literature of the era before the significant importation of continental cultural institutions had begun (pre-eighth century CE). While National Learning was mostly a literary phenomenon during the eighteenth century, its scholars shifted to an emphasis on Shinto religious beliefs and practices during the nineteenth century. Finally, the eighteenth

century saw the rise of European science in the form of Dutch Learning. With the support of the eighth shogun, Yoshimune (1684–1751), scholars began to study the Dutch language with the goal of translating scientific texts (mostly dealing with astronomy, medicine, navigation, and gunnery) into Japanese. These scholars translated dozens of important texts by the end of the eighteenth century.

Faced with the emergence of these competing forms of scholarship, Matsudaira Sadanobu promulgated his Ban on Heterodox Studies in 1790. The ban restored the centrality of Neo-Confucianism within the curriculum of the shogunal academy and forbade the teaching of all other forms of learning (including the Confucian studies of Jinsai and Sorai). The success of the ban, however, was limited. By reasserting the importance of Neo-Confucianism in the shogunal academy, the ban influenced schools in the provinces to do the same during the nineteenth century. These schools served functions similar to the shogunal academy, with the exception that their students were prepared for service in domainal governments. As Neo-Confucianism returned to the central position that it had enjoyed in the seventeenth century, its adherents and critics alike began to identify it with the shogunal government of the Tokugawa family. Thus, despite the ban, Mito Learning, National Learning, and Dutch Learning continued to thrive, especially as forms of scholarship appealing to opponents of the government. In fact, Mito Learning and National Learning became influential ideologies that supported the overthrow of the Tokugawa government in 1868.

Late Tokugawa Shintoism

Shinto, or the “way of the gods,” is the indigenous religion of Japan. Throughout its long history, it has shaped the development of Japanese aesthetics, society, and politics, especially in recent centuries. In the late Edo period (1603–1868), Shinto was instrumental in destabilizing the Tokugawa shogunate and helped prepare the way for the Meiji Restoration of 1868.

Shinto is practiced locally in the popular veneration of clan deities, mythical figures, and regional natural phenomena. It is also a formal religion, with liturgies, scriptures, shrines, and seasonal rituals performed by ordained priests. At the national level Shinto is a cultural artifact, intimately connected with state power and the cult of the imperial household. Traditionally, Japanese emperors have been revered as Shinto high priests and deities in their own right. Owing to the customarily fluid nature of Japanese religious practice, the “way of the gods” has tolerated and even aided the proliferation of foreign religions such as Buddhism and Confucianism, but of Japan’s three major religious traditions, Shinto always has been the one most closely linked to ethnic nationalism.

Tokugawa Ieyasu (1542–1616) used the doctrines of the Yoshida Shinto sect to help unify a fragmented Japan. While the political regime he founded was in practical terms a Neo-Confucian order, Ieyasu acquired imperial legitimacy through his investment as shogun (generalissimo) and was careful to have himself enshrined as a Shinto deity. In this way, he was able to exploit indigenous custom in order to secure his dynasty’s supremacy despite the fact that shoguns technically served under the emperor. Ironically, nativist thinking centuries later worked to undermine the legitimacy of the Tokugawa regime, as scholars of National Learning worked to revitalize the divine sovereignty of the imperial house. Hirata Atsutane (1776–1843) was instrumental in reviving Shinto practice in the early nineteenth century, and those who embraced Shinto came to openly question the spiritual legitimacy of the shoguns. The Tokugawa position was also damaged by the fact that the regime had been ineffective in dealing

FROM HIRATA ATSUTANE, OUTLINE OF THE ANCIENT WAY

Hirata Atsutane (1776–1843) was one of the scholars instrumental to the revival of Shintoism in the early nineteenth century; this revival encouraged the restoration of the emperor and rejection of shogunal rule. The following is an excerpt from one of Atsutane’s writings:

“People of the world without fail point to our country and call it the country of gods. . . . Our country was procreated by the gods by the special grace of the heavenly deities, and its difference from all other foreign countries is as wide as the distance between heaven and earth. Our country is so precious that it is beyond comparison. The fact that our country is a country of gods is not open to dispute, and even the lowest of men and women are unmistakably descendants of gods. However, pitiful indeed are those who do not know our glorious heritage.”

with deteriorating domestic and foreign problems, chief of which was the aggressiveness of Western traders demanding access to Japanese ports. After 1845, Shinto became an integral part of a political ideology that sought both the restoration of the imperial house in favor of the shogunate and stronger resistance to the West.

The most forceful of the anti-Western restorationists were the midlevel samurai who called themselves *shi shi*, or “men of high principle.” Led by radicals such as Yoshida Shoin (1830–59) and united by the rallying cry “*sonno joi*” (“revere the emperor, expel the barbarian”), these men sought to establish a new political order centered on the person of the emperor and were willing to use violence to achieve their goals. Members of the religious arm of this movement, Fukko Shinto (Restoration Shinto), believed that imperial restoration would also reestablish the primacy of Shinto among Japan’s various religions.

The forced opening of Japan by the United States to Western trade in 1853–1854 triggered the political crisis that eventually led to the Meiji Restoration in 1868. From this event through the end of World War II, an innovation known as State Shinto (Kokka Shinto) played an ever-expanding role in defining Japanese power and identity. Using the imperial throne as the locus of state sovereignty, Emperor Mutsuhito and his inner circle invoked Shinto and the cult of the divine emperor to unify the Japanese people, to exhort them to ever greater achievements in their work, and, if need be, to sacrifice themselves in war for the good of the state.

Shintoism during the Meiji Period

During the Meiji period (1868–1912), Shintoism in Japan became more than a religion in a conventional sense as a result of its connection with emperor veneration. After the Meiji Restoration of 1868 when the imperial court was restored, the focus of Shintoism moved from local deities and nature worship to ancestor worship and reverence for the emperor. It became a quasi religion in that for many Japanese, worshipping the emperor was a matter of unquestionable patriotic duty rather than a personal faith that they could choose or not choose to develop. Through state rituals and education, Shintoism provided a sense of unity and national solidarity and contributed to the stability of the government throughout the imperial period.

Just as the Meiji Restoration occurred in response to the weakness of Tokugawa feudalism, the revival of Shintoism was a reaction to the chaotic situation in early Meiji Japan. Disruptive forces such as social turmoil, competing indigenous ideas, and the introduction of Western ideologies such as liberalism and individualism demanded that the Meiji leaders create a basis for unity and solidarity for the Japanese. They found

a powerful model for Japanese spiritual life in the teachings of the eighteenth-century National Learning scholar Motoori Norinaga (1730–1831), who rejected Chinese Confucianism and sought inspiration in Japan's ancient literary and religious heritage. Given that the emperor was considered the direct descendant of the supreme deity Amaterasu Omikami, the government used the emperor's divinity to cultivate a sense of patriotic responsibility for the ruler. The Japanese Imperial Constitution (1889) made it clear that the emperor was the state sovereign and a "sacred and inviolable" entity.

Shintoism gained its suprareligious character because of the failure of the Great Promulgation Campaign (1870–1884) in which Shinto priests, elevated to the status of officials in the Department of Divinity, aimed to establish a state religion based on Shintoism. The government abolished the department and its plans to reformulate Shintoism, primarily because it faced popular riots and uprisings of Buddhist monks against the campaign. In 1900 Shintoism gained the special legal privilege of having direct supervision and coordination from the Bureau of Shinto Shrines in the Department of Home Affairs. In contrast, religions such as Buddhism, Christianity, and sectarian Shinto came under the jurisdiction of the Bureau of Religions.

Shintoism was made inseparable from government and education, as exemplified by the term *saisei icchi* (the unity of rites and politics). Although there was no formally accepted textbook on Shintoism, the Imperial Rescript to Soldiers and Sailors (1882) and the Imperial Rescript on Education (1890) instead became the moral doctrine for students and soldiers. Shinto teaching permeated family life, school, rites, and rituals. The government put almost all aspects of Shintoism under national and local supervision, from the appointment of Shinto priests to the permission to build *torii* (the gateway to Shinto shrines). Throughout Japan, various locally enshrined Shinto gods were united in the name of the national faith. Shrines were classified into 12 grades, the highest of which was the Ise Grand Shrine enshrining Amaterasu Omikami.

The basis of divinity originated in the imperial bloodline rather than political power or moral philosophy. This ideology encouraged the

subordination of non-Japanese ethnic nations such as Taiwan and Korea, despite the official claim that they had received the equal benevolence of the emperor. Through the cult of the divine ruler, the Meiji government extended its hand abroad to create cultural hegemony, which nonnative Japanese were forced to accept.

YASUKUNI SHRINE

Under the command of Emperor Meiji in 1879, the Yasukuni Shrine, originally known as Tokyo Shōkokusha, was reconstructed for commemorating the war dead. During the Meiji period, the shrine gained a patriotic significance of honoring the spirit of Japanese war dead in civil wars, the Sino-Japanese War, and the Russo-Japanese War. The commemoration of Class A war criminals convicted in the Tokyo Tribunal (1946–1948) as well as the visits to the Yasukuni Shrine by cabinet members places the shrine at the center of controversy, particularly in diplomatic relationships with China and South Korea.

■ Introduction: Trends in European Thought

In the mid-1700s, the European intellectual movement known as the Age of Enlightenment was beginning to reach its peak. In 1749 the Baron de Montesquieu published his *Spirit of the Laws*, in which he introduced the concept of the separation of powers as a safeguard for liberty; Voltaire, Europe's best-known writer, produced a steady stream of essays, criticism, histories, and novels, including his best-selling *Candide* in 1759; in 1761 Jean-Jacques Rousseau published *Émile*, at once a novel and a groundbreaking treatise on education, and a year later published his *Social Contract*, which set forth the idea of popular sovereignty as the only basis for legitimate government; in 1764 the Italian Cesare Beccaria published *On Crime and Punishments*, a scathing attack on the cruelties and injustices of Europe's legal systems; and in 1776 the Scotsman Adam Smith published *The Wealth of Nations*, which defended individual economic freedom and free trade. Between 1750 and 1765 editors Denis Diderot and Jean d'Alembert oversaw the completion of the multi-volume *Encyclopédie ou dictionnaire raisonné des sciences, des arts et des métiers*, a collective enterprise involving many dozens of writers. It was simultaneously a source of factual informa-

tion, a critique of eighteenth-century society, and a statement of the Enlightenment's fundamental principles.

These principles, set forth in the writings of the *philosophes* (philosophers), the somewhat inaccurate name used to describe the Enlightenment's leading figures, were inspired by the achievements of Europe's scientific revolution, in particular the work of Isaac Newton, whose *Mathematical Principles of Natural Philosophy* (1787) set forth the law of universal gravitation and affirmed the power of human reason to understand the natural laws that governed the universe. Newton's laws suggested to the *philosophes* that equally spectacular results could be achieved if reason could be applied to a whole range of human endeavors other than science. In their eyes, eighteenth-century government, economic policy, education, legal systems, agriculture, and systems of labor, to name a few, were corrupt, unfair, immoral, and cruel. But if these institutions and practices could be brought in line with their underlying "natural" principles, then progress would occur. For Voltaire, progress meant small victories in the battle against religious bigotry, warfare, and various forms of human cruelty. For others such as the Marquis

de Condorcet (1743–1794), the author of *The Progress of the Human Mind*, progress meant a utopian future of peace, equality, robust health, and prosperity for every part of the world. In any case, according to the philosophes, human beings no longer were consigned to passively accept the status quo.

The Romantic movement of the late eighteenth and early nineteenth centuries was a product of the emotional upheavals connected with the era of the French Revolution and Napoleon and a reaction against the Enlightenment. Its proponents challenged the “shallow rationalism” of the philosophes, emphasizing instead the importance of imagination, emotion, and personal perspective in the creative process. The Romantics also celebrated individual differences rather than universal laws and viewed history as a source of inspiration rather than a useless relic to be overcome and forgotten. Romantic poets and artists had a wide following on both sides of the Atlantic in the early 1800s, and their interests and convictions inspired important scholarly work in the study of languages, folklore, and history, especially of the Middle Ages. Romanticism also lent support to the deepening of religious sentiment among many Americans and Europeans in the early nineteenth century.

Even in the heyday of Romanticism, however, the Enlightenment’s faith in science, reason, and progress persisted. The Enlightenment era’s debates on politics, which were intensified by the American Revolution, the French Revolution and the conservative reaction that followed, continued but became more refined and systematic. In contrast to the philosophes’ search for the universal principles underlying just government, writers of the early 1800s were determined to defend particular points of view. The words “liberalism,” “conservatism,” “radicalism,” “republicanism,” “socialism,” “constitutionalism,” “monarchism,” and “nationalism” all were coined between 1819 and the 1840s as writers discussed their attributes and pros and cons. The Enlightenment’s humanitarianism and faith in progress (along with the energy provided by evangelical Christians) can be seen in the movements on behalf of abolition, temperance, women’s rights, and public sanitation in the early 1800s. The Enlightenment’s influence

also can be seen in the writings of Robert Owen, Charles Fourier, and Henri de St. Simon, all of whom were “utopian” socialists with dreams of perfectly organized and perfectly just societies.

Most of all, the strength of the Enlightenment tradition can be seen in the ongoing progress of science. Important discoveries were made in the study of heat, chemistry, electricity, and geology. Scientific and mathematical research became a focus of university education in Germany, France, and other parts of Europe. Writers in the early 1800s sought to apply the principles of scientific research to the study of human society. This can be seen in the “positive” philosophy of Auguste Comte (1798–1857) and the “utilitarian” philosophy of Jeremy Bentham (1748–1832), who devised a system of “felicific calculus,” based on 12 human pains and 14 pleasures to determine the moral value of any action or political policy. Most famously, Karl Marx was determined to separate his “scientific” socialism from earlier utopian socialists by carefully basing his theories on history and economic theory.

The works of Marx, who wrote the *Communist Manifesto* along with Friedrich Engels in 1848, his magnum opus *Capitalism* in 1864, and numerous other works, along with the writings of Charles Darwin, *On the Origin of Species* (1859) and *The Descent of Man* (1871), were turning points in the history of nineteenth-century thought. Aside from Marx’s critique of capitalism, his theories of class conflict and economic determinism provided a controversial new perspective on history, politics, and human behavior. His theories of revolution set off passionate debates within the socialist camp, with anarchists, evolutionary socialists, Christian socialists, and democratic socialists all departing from Marxian orthodoxy. Darwin’s theory of evolution, which was based on the struggle for existence and the principle of natural selection, provoked immediate opposition from certain religious groups that upheld the biblical account of creation. More importantly, Darwinism, when applied to social issues, lent support to a host of movements including free trade, imperialism, eugenics, nationalism, militarism, and “scientific” theories of race.

In the 1890s and early 1900s, certain discoveries in physics, especially Albert Einstein’s

theory of relativity and various physicists' work on radioactivity, cast doubt on long-held scientific views of cause and effect, space and time, and matter. Sigmund Freud's writings on the role of the subconscious in human behavior cast doubt on the Enlightenment's faith in humans' basic rationality. But the astounding scientific, medical, and technological breakthroughs of the late nineteenth century, along with rising standards of living, the spread of public education, and the expansion of Western power across the globe, gave further strength to the Enlightenment idea of progress. It took the slaughter of World War I, the misery of the Great Depression, the Nazis' mass murder of Europe's Jews, and the astounding casualties and cruelties of World War II before this Enlightenment article of faith came to be doubted and widely abandoned.

—James H. Overfield

Romanticism

Romanticism is the theory of art, music, or literature that values emotion above reason and finds spiritual growth in simple, immediate responses to ordinary phenomena, especially natural phenomena. It arose in the late eighteenth century in direct reaction to the Enlightenment, which the early romantics saw as too singularly devoted to reason and analysis. There were two main romantic movements, English and German. They had very little to do with each other. English romanticism had almost no influence on the German variety, but some of the middle figures in German romanticism, notably the philosopher Friedrich Wilhelm Joseph von Schelling (1775–1854), influenced the later English romantics through the works of poet and critic Samuel Taylor Coleridge (1772–1834).

Besides Coleridge, the major exponents of English romanticism were artist and poet William Blake (1757–1827); poet John Keats (1795–1821); poet Percy Bysshe Shelley (1792–1822) and his wife, novelist Mary Wollstonecraft Shelley (1797–1851); poet George Gordon, Lord Byron (1788–1824); and poet William Wordsworth (1770–1850). Among the best-known works of the English romantics are Blake's *Songs of Innocence and Experience*, Keats's "Ode on a Grecian Urn," Mary Shelley's *Frankenstein*, Coleridge's "Rime

of the Ancient Mariner," Byron's *Childe Harold*, Percy Shelley's *Queen Mab: A Philosophical Poem*, and Wordsworth's 1807 two-volume collection of his poems. Like all romanticism, the English variety is profound in its respect for nature. As such, romantic writers are progenitors of the environmentalist activism of the late twentieth and early twenty-first centuries.

German romanticism was more diverse, longer lived, and arguably, outside the English-speaking world, more important than its English counterpart. Among its founders in the 1790s was the greatest author of German classicism, Johann Wolfgang von Goethe (1749–1832), who had also been instrumental in founding the Sturm und Drang (storm and stress) movement in the 1770s. Goethe and his close friend, poet and dramatist Johann Christoph Friedrich von Schiller (1759–1805), collaborated in 1797 to

➤ “FOREST LONELINESS” AND THE GERMAN ROMANTICS

Among the most important romantic notions was what the Germans called *Waldeinsamkeit* (pronounced “vahl-INE-zahm-kite”). The word literally means “forest loneliness,” but the idea behind it is not easily translatable. It refers to the exalted feeling of freedom that reflective individuals get when calmly alone, as when wandering deep in the woods. Individualism, autonomy, and personal freedom were all part of Enlightenment thought as well, notably in the ethical works of German philosopher Immanuel Kant (1724–1804), but in German romanticism these concepts truly flourished. *Waldeinsamkeit* is evident in Friedrich’s paintings and Thoreau’s *Walden*. Tieck, Heine, many other contemporary German poets, and even Emerson each wrote a poem titled “*Waldeinsamkeit*.”

—Eric v.d. Luft

publish *Xenien*, a controversial series of 207 epigrammatic couplets. Other early German romantics include philosopher Johann Gottlieb Fichte (1762–1814), theologian Friedrich Daniel Ernst Schleiermacher (1768–1834), poet Friedrich Hölderlin (1770–1843), and scholars August Wilhelm von Schlegel (1767–1845) and his brother Friedrich (1772–1829). All of these writers were champions of individual freedom.

Folklore was a major influence on the development of German romanticism. Ludwig Tieck (1773–1853) became famous for fantasies such as *Blond Eckbert*. Clemens Brentano (1778–1842) and Ludwig Achim von Arnim (1781–1831) collected stories in *The Boy’s Horn of Wonder*. The anthropologist brothers Jakob (1785–1863) and Wilhelm Grimm (1786–1859) offered their famous anthology of fairy tales. The stories of Ernst Theodor Amadeus Hoffmann (1776–1822) furnished the material for the opera *Tales of Hoffmann* by French composer Jacques Offenbach (1819–1880). Comedic fictional characters, such as Adelbert von Chamisso’s (1781–1838) Peter Schlemihl, Joseph von Eichendorff’s (1788–1857) Ne’er-Do-Well, and Heinrich von Kleist’s (1777–1811) Adam in *The Broken Jug*, became new folk heroes and antiheroes.

Religious tradition and cultural nationalism also exerted strong influence. Much German romanticism expresses intense yearning (*Sehnsucht*) for return to an imagined golden era of ages past. Poet and essayist Friedrich von Hardenberg (1772–1801), known as Novalis, craved the golden era of medieval Roman Catholicism in which the Holy Roman Empire and a common spiritual culture unified Europe.

French and American manifestations of romanticism were latecomers. French leaders include poet and novelist Victor Hugo (1802–1885); novelists Henri Beyle (1783–1842), known as Stendhal, and Alexandre Dumas Sr. (1802–1880); and poets Alphonse de Lamartine (1790–1869) and Alfred de Musset (1810–1857). American leaders include poet Henry Wadsworth Longfellow (1807–1882), transcendentalist philosophers Henry David Thoreau (1817–1862) and Ralph Waldo Emerson (1803–1882), and novelists James Fenimore Cooper (1789–1851), Nathaniel Hawthorne (1804–1864), and Herman Melville (1819–1891).

Important romantics who excelled in fields other than literature include German composer Ludwig van Beethoven (1770–1827), French composer Hector Berlioz (1803–1869), Hungarian composer Franz Liszt (1811–1886), Polish composer Frédéric Chopin (1810–1849), German painter Caspar David Friedrich (1774–1840), Spanish painter Francisco Goya (1746–1828), French painters Eugène Delacroix (1798–1863) and Théodore Géricault (1791–1824), and English painter Joseph Mallord William Turner (1775–1852).

German philosopher Georg Wilhelm Friedrich Hegel (1770–1831) found merit in both the Enlightenment emphasis on reason and the romantic emphasis on emotion. He attempted to reconcile these two apparently contradictory ways of thinking in order to create an absolute idealism that would recognize the indispensability of both reason and emotion for the human spirit. Influenced by Hegel’s philosophy of history, poet and social critic Heinrich Heine (1797–1856), who is often regarded as Germany’s first political poet, was the bridge between romanticism and the liberal, nationalistic Young Germany movement of the 1820s and 1830s.

Positivism

Positivism is a broad movement of thought that marked the second half of the nineteenth century in Europe. The name derives from the fact that thinkers returned to the appreciation of positive facts so as to restore the world of nature, which the idealists had reduced to a mere representation of the ego. Positivism placed greater stress on immediate experience and on the positive data obtained through the senses.

Positivism emerged in France under Auguste Comte (1798–1856), evolving from English empiricism, which argued that experience was the only source of human knowledge. The new school of thought held that reality mechanically evolves from inferior forms until it attains consciousness in humans. According to Comte, historical observations on the process of human society show that humans have passed through three stages: first is the theological state, in which nature was mythically conceived, and the individual sought the meaning of natural phenomena from supernatural beings; second came the metaphysical stage, in which nature was conceived of as a result of obscure forces, and the individual sought the explanation of natural phenomena from them; third came the positive stage, in which all abstract and obscure forces are discarded, and natural phenomena are explained by their constant relationships. Comte extended the law of the three stages to include all reality.

Comte elaborated a political philosophy designed to simultaneously promote order and progress. He announced the development of a new religion of humanity to provide an emotional and spiritual foundation for his philosophy.

To promote order and progress, Comte suggested the individual be subordinated to society. He also posited the desirability of gradual social change. He believed that political problems should be subject to the same procedures that scientists used to resolve scientific questions. That is, politics should be in the hands of experts and technicians who could form expert opinions and thereby mediate between people and their rulers. In other words, he wanted to create a technical elite of political experts, who were above politics and, hence, above the blind desires of “the public.”

European positivism influenced both politics and economics. An extreme form of democracy arose, proclaiming absolute rule of the people. Freedom was understood as the full liberty of the individual, as long as there was no harm to the rights of others. The laissez-faire doctrine in economics led to Manchesterism, a theory based on the liberal principle of economic freedom, which arguably allows employers to pay the lowest possible wages without any moral responsibility toward the worker.

Positivism in the second half of the nineteenth century became an important social and political philosophy in Latin America, where it played a more progressive role than it did in Europe. People who embraced it believed that it would bring technical progress such as railroads and industrialization to their countries. It met the needs of many Latin American intellectuals who rejected Spanish and Portuguese culture and were trying to prove their independence by adopting French ideas. They considered Catholicism to be a tool of Spanish imperialism, which had kept Latin America in a state of amoral, chaotic backwardness. Positivism in Latin America introduced new methods in religion, philosophy, and especially politics and education. Scientific knowledge became the main objective of educational reform. In the field of politics, Latin American positivism was derived from its application to political problems, with solutions involving a utilitarian and pragmatic approach.

Social Darwinism

Social Darwinism is the political theory that English philosopher Herbert Spencer (1820–1903) developed in the 1850s, based on then current ideas of biological evolution. Its first important expression was Spencer's "Progress: Its Law and Causes" in the April 1857 issue of the *Westminster Review*. To call it any kind of Darwinism is anachronistic, since Spencer's article predated by two years Charles Darwin's (1809–1882) *On the Origin of Species*, the first and central text of Darwinian evolution. It is called social Darwinism because Darwin's biological analysis and Spencer's politics fit together well and mainly because Darwin remains more famous than Spencer. That label was never used by anyone contemporary with the movement but was coined in the 1930s by its detractors. Spencer himself called his theory social evolution.

The basic tenet of social Darwinism is that what happens in society ought to be analogous to what happens in nature. According to the biological theory of natural selection, the strongest, best-adapted, and most clever animals and plants survive, procreate, and evolve into even stronger, better-adapted, and more clever species, while weaker, less intelligent, and less well-adapted members die and allow their species to become extinct. Spencer maintained that human governments ought to allow similar life-or-death competition rather than intervene to help anyone disadvantaged physically, mentally,

or economically. Other social Darwinists went even further, claiming that to help the poor or the weak was morally wrong. Inferior people should be left alone so that they would either die or toughen up and survive.

Social Darwinism in its time appealed alike to conservatives and liberals, although nowadays it would be taken as a mostly conservative viewpoint. Its adherents saw it as a logical extension of the classic natural law theory of St. Thomas Aquinas (ca. 1225–1274) and Hugo Grotius (1583–1645). It sharply opposed the utilitarian positive law theory of Jeremy Bentham (1748–1832) and John Stuart Mill (1806–1873). As incorporated in the writings of American economist William Graham Sumner (1840–1910), it frankly supported laissez-faire capitalism.

Both Darwin and Spencer were influenced by Thomas Robert Malthus (1766–1834), whose 1798 book *An Essay on the Principle of Population* argued that the Earth can only feed a certain number of people and that war, poverty, famine, disease, and other apparent evils are actually beneficial because they check population growth.

The motto of those who encouraged natural selection in human society was "survival of the fittest," a phrase coined by Spencer, not Darwin. Their goal was to relieve the so-called white man's burden by eliminating undesirable individuals and families from breeding populations. Relating Darwinian biology to political and ethical theory was easy for imperialist thinkers of the Victorian era, who believed in the innate superiority of Europeans. Rather than care for the domestic poor or provide humane, respectful colonial policies, the moral duty of powerful white Europeans was to exploit native peoples to the greatest possible extent and thus further enhance European culture. In 1872 English economist Walter Bagehot (1826–1877) wrote in *Physics and Politics* that cultured nations evolve only through their innate strength.

In 1883 Darwin's cousin Francis Galton (1822–1911) coined the term "eugenics" from two Greek words meaning "well born." Galton founded both eugenics and medical genetics on Darwinian principles, envisioning a future world in which only strong, intelligent whites would reproduce. He was a major influence on

➤ ANDREW CARNEGIE

(Library of Congress)

Scottish American industrialist and philanthropist Andrew Carnegie (1835–1919), a friend of the prominent social Darwinist thinkers Herbert Spencer (1820–1903) and William Graham Sumner (1840–1910), was a zealous advocate of social evolution. Carnegie believed that the rich were morally obliged to give away their money, not to help the poor but to improve society. His philanthropy was never in the form of handouts, which might encourage

sloth and social deterioration, but always in the form of incentives for intelligent people to work hard to better themselves. To promote self-education, he established 2,509 libraries. In 1910 the Carnegie Foundation for the Advancement of Teaching published *Medical Education in the United States and Canada*, known as the Flexner Report. The report branded over half of American medical schools as inadequate and caused them to close.

—Erik v.d. Luft

Marie Stopes (1880–1958), a conservative, anti-Semitic, British eugenicist who advocated birth control, involuntary sterilization, and abortion as means of social control to prevent so-called inferior women from reproducing. The eugenicist extremes of social Darwinism are evident in the excesses of Nazism and other flagrantly racist atrocities of the twentieth century.

Spencerian social evolution informed the works of English author Rudyard Kipling (1865–1936) and American novelist Edgar Rice Burroughs (1875–1950), creator of the *Tarzan of the Apes* series. They all believed that innate virility would carry white men through the toughest environmental challenges and enhance their natural superiority over other races.

Darwinism and Religion

When Charles Darwin published *On the Origin of Species* in 1859, very few people—among the public and scientists alike—were concerned about a serious rift between science and a religious point of view. When such conflicts would arise, attempts were made to reconcile the two fields of knowledge. As Benjamin Silliman, a scientist and popular lecturer in the United States in the 1840s pronounced, “Truth is always truth. . . . And no one truth can ever be in conflict with any others.” Numerous scientific contemporaries of Silliman, such as Michael Faraday, a key figure in the development of the theory of electricity, were highly pious. Indeed, many of the era’s natural historians, including Darwin, had training or livelihoods as clergymen.

Throughout most of the nineteenth century, even after the publication of Darwin’s theory, the standard point of view on the relationship between science and religion, as offered in public lectures, articles, and books that treated the topic, involved the “argument from design,” which simply stated that scientific discoveries of the intricate workings of nature only further revealed the genius of the Creator. The complexities of nature indicated purposive structures or designs in the world that implied a designer. The

world was not dead matter but rather a creation. Such a point of view had been posited, to great success, in works such as William Derham's *Physico-Theology* (1713) and a century later in William Paley's *Natural Theology* (1802). Following this approach, by the late nineteenth century, as the shock of evolutionary theory subsided, versions of "theistic evolution" became popular that welded Darwin's theory to the argument from design by suggesting that a divine force somehow guided the evolution of species.

Yet such attempts at harmonizing the two fields required a gradual rejection of a biblical literalist viewpoint. In 1650, Archbishop James Ussher (1581–1656) published *The Annals of the Old Testament*, a work that placed the biblical date of creation at October 26, 4004 BCE. In the eighteenth century, Bibles published in Britain often included Ussher's chronology. New theories about geology and evolution brought such literalism into question. In 1778 Georges-Louis Leclerc, Comte de Buffon (1707–1778), published *Les Époques de la Nature*, which stretched the age of the earth from the approximately 6,000 years posited by Ussher and other biblical literalists to 75,000 years. Assuming that the earth had been cast off from the sun, Buffon estimated its rate of cooling to calculate its age. As such theories were assessed, many men of learning sought to reconcile scripture with the geological record, and alternative theories of geology contended and purported to reveal, for example, the truth of the biblical flood. To explain the fossil record and its gaps, the French naturalist and zoologist Georges Cuvier (1769–1832) proposed a model of catastrophism, which stated that the earth had gone through many epochs, each with its unique flora and fauna that had eventually perished in a cataclysm. Charles Lyell (1797–1875), in his *Principles of Geology* (1830–1833), proposed a theory of uniformitarianism whereby slow geologic processes had steadily reshaped the earth's surface and features. The earth was immensely old, perhaps millions of years old. Lyell's theory did not lend itself easily to biblical literalism. Grappling with the idea of the earth as millions of years old led many to argue that the Bible's six days of creation referred to very long phases that could be thought of as metaphorical days. Biblical literalism could not

be salvaged easily, but a school of "scriptural geologists" continued to produce works such as that of the evangelical vicar William Galloway (1811–1903), whose *Science and Geology in Relation to the Universal Deluge* (1888) was just one of many pamphlets he wrote attempting to reconcile biblical and geological accounts.

Darwin's theory, as published, was not avowedly atheistic; he was content to show that a slow process involving the transmutation of species made more sense than a theory of the separate creation of each species as final and distinct. Yet he notes that his theory takes off from some distant event when life was first "breathed"—a phrase he uses several times—into one or perhaps a few primordial life forms. Beyond that, Darwin insisted that natural forces such as the struggle for survival and chance variations in species could explain the development of all the earth's flora and fauna. Unlike the earlier evolutionary theory first published in 1809 by Jean-Baptiste Lamarck (1744–1829), there was no guiding principle, no teleology to the process. Adaptations occurred not purposefully but instead from chance variations subject to random population dynamics. While Darwin did suggest a development of simple to complex life forms, he did not see this as evidence of intention or purpose; chance variations and their possible usefulness, not a designer's intent, led to the variety and growing complexity of life on the planet. Furthermore, Darwin's theory indicated that humans had no unique position as the pinnacle of creation on earth but instead were shaped by the same forces as other species (a point argued much more crisply in Darwin's *The Descent of Man* [1871]). Darwin's theory, as stated, spoiled the premise of the argument from design.

Some of Darwin's defenders took on an openly materialistic and atheistic worldview and engaged in great debates with defenders of the faith, but others offered a version of evolution that involved reconciliation. Herbert Spencer (1820–1903), for example, insisted that evolution and the idea of progress were interlinked, lending support to the laissez-faire social and political view popularized as social Darwinism: the struggle for wealth would bring about society's perfection, just as evolution led to the

creation of higher species. Botanist Asa Gray (1810–1888), Darwin's great defender during the nineteenth-century debates in the United States, presented the "theistic evolution" position that natural selection was guided by a divine hand.

Given the popularity of such approaches as Spencer's and Gray's—which harmonized Darwin's insistence on variations and the transmutability of species with the possibility of a guiding divine force—serious clashes between religion and science awaited the time that biblical literalists again would become a social force to reckon with. Rather than turn to biblical literalism or even to the bible as metaphor, many Christian modernists sidestepped the issue and chose a stance with antique pedigree: the truths of religion and those of science were of different orders and did not need to be reconciled. This rankled many in the Christian fundamentalist movement that developed in the late nineteenth and early twentieth centuries in Britain, Australia, and the United States. The tenets of fundamentalism, which included biblical literalism and a clear-cut moral vision, were committed to print in a series of pamphlets called *The Fundamentals* between 1905 and 1915. A serious clash became even more imminent following World War I when biblical literalism was mixed with an ethical critique of social Darwinism and its excesses such as the eugenics craze and social Darwinism's purported influence on German militarism. The religious promptings of constituents, a populist bent, and genuine ethical concerns led William Jennings Bryan to argue the case for banning the teaching of the theory of evolution in the State of Tennessee in 1925.

Theories of Race

Scientific ideas of racial classification occupy the dangerous middle ground between impartial scholarly anthropology and the social blight of racism and prejudice. Anthropology began in Germany and Britain in the late eighteenth century and immediately formulated what the British called scientific racism. The plan was to categorize various human types according to a system such as that of Swedish botanist Carolus Linnaeus (1707–1778). Against this plan, German philosopher Johann Gottfried von Herder (1744–1803) asserted in 1784 that the concept of race was not applicable to the human species. American Presbyterian clergyman Samuel Stanhope Smith (1750–1819) argued that there was only one human race and that differences in skin color and other distinguishing racial characteristics could all be attributed to environment. English physician Charles White (1728–1813) polemicized against Smith, claiming that the natural differences among human races were nearly tantamount to definitions of separate species. Both science and popular opinion overruled Herder and Smith for the next 200 years.

The motivation for classifying humans was as much prejudice as science. Early anthropologists sought to bolster the popular bias that the white European male was the ideal human type and that all other humans were deviations from this norm. They claimed that their classification was natural and inexorable, not imposed or arbitrary. Even Herder and Smith, who each believed that humans could not be classified in a Linnaean way, still recognized human physical differences and agreed with that goal.

The systematic concept of race is post-Linnaean and was not discovered as a biological reality but was developed or almost invented by white European and American male scientists as a social construct. The ancient Greeks, Romans, and Hebrews were equally prejudiced against certain groups, but they identified individuals

CHARLES BELL'S ANATOMICAL COMPARISON OF RACES

(Charles Bell. *The Anatomy and Philosophy of Expression as Connected with the Fine Arts*, 1877)

Charles Bell's anatomical/physiological argument for race as a biological reality and for the natural superiority of the white European male is epitomized in this inset illustration from his 1806 book, *Essays on the Anatomy of Expression in Painting*.

Bell's drawing shows Marcus Vipsanius Agrippa (ca. 63–12 BCE) facing an unnamed, perhaps composite, African. Bell argues in the accompanying text that God designed the European's mouth primarily for oratory but the African's primarily for eating. Darwin's 1872 book *The Expression of the Emotions in Man and Animals* disagreed with Bell about God's intelligent design but credited Bell's study of facial expressions with contributing to racial theory.

—Eric v.d. Luft

by their distinct colors, hairstyles, modes of dress, habits of speech, and other external signs, and they did not classify. Strict racial partition was a new idea in the wake of intellectual Europe's fascination with the Linnaean system and subsequent obsession with classification. Classificatory racism was an outgrowth of the Enlightenment. It received a significant boost in 1798 through the publication of *Essay on the Principle of Population* by English political economist Thomas Robert Malthus (1766–1834).

Scientific racial theory began with Dutch comparative anatomist Petrus Camper (1722–1789) and was furthered by Swiss theologian Johann Kaspar Lavater (1741–1801), German anthropologist Johann Friedrich Blumenbach (1752–1840), and Scottish anatomist and surgeon Charles Bell (1774–1842). Camper originated racial classification based on measurements of bones, especially skulls, rather than color.

English physician James Cowles Prichard (1786–1848) was the leading theorist of race

between Blumenbach and English naturalist Charles Darwin (1809–1882). But Prichard did not begin to publish on race until 1813, expanding upon his 1808 medical dissertation, and by that time much of the medical, anatomical, and anthropometric basis of racial theory had already been established by Camper, Blumenbach, and Bell. In this tradition, Darwin argued that pure races existed, with some superior to others, according to their evolved characteristics.

English physician and neurologist Thomas Laycock (1812–1876) acknowledged two works of the Scottish painter, architect, and interior designer David Ramsay Hay (1798–1866) as having influenced his conception of ideal human heads and faces and their various defective forms. Hay's views resembled and perhaps were derived from Bell's. Laycock used Hay to liken the African head to that of the “degenerate European.” English physician John Langdon Haydon Down (1828–1896), also influenced by Bell's version of scientific racism, correlated various levels of observed mental deficiency with various racial types. Down himself called “Mongolian idiocy” what is currently called Down syndrome. He also identified idiots by their apparent similarities to Malays, Ethiopians, and American Indians.

These rigid views of race pervaded the nineteenth century and remained mostly unchallenged until Anglo-American anthropologist Ashley Montagu (1905–1999) began investigating race in the 1920s.

Racism—Theory and Practice in the United States

There is some debate as to the origins of racism in the United States. Some scholars argue that

colonial distinctions were made between Christians and “heathens” rather than between different races, while others maintain that race was always an important distinguisher in America. Those who believe that religious distinctions were primary maintain that slavery was not originally a race-based system and that racism developed after the institution was established in order to dehumanize slaves and rationalize the practice. Others, however, argue that racism predated slavery and was central to the establishment of the institution. Regardless of whether or not racism existed among colonial Americans, there is little doubt that by the turn of the nineteenth century distinctions were made between racial groups and that these distinctions were thought to be meaningful.

By the early 1800s most Americans believed that a person’s race determined a great deal about not only their physical traits and capacities but also their intellectual, emotional, and spiritual traits and capacities. There was, they believed, a hierarchy of races, determined by the various races’ inherent and unchanging qualities. This theory was supported by the development of so-called scientific racism during the nineteenth century. Many intellectuals took Darwin’s theory of evolution and applied it to human societies, claiming that Europeans were more advanced in terms of their evolutionary development, which was evidenced by their superior social and intellectual capacities. This became known as social Darwinism.

Science was not the only tool upon which racists drew, however. Religion was also used to justify prejudice, and religious explanations for racial hierarchies were also popular. One such explanation was based on a biblical story of Ham, one of Noah’s sons. The ninth book of Genesis says that Noah cursed Ham’s son Canaan after Ham saw his father drunk and naked. Many Americans believed that Africans were the cursed descendents of Ham, which provided religious justification for their persecution and enslavement. Another popular religious justification for racism was the theory of polygenesis. According to this theory, the story of Adam and Eve only described the creation of white people. Consequently, other races were created at a different time or when God created the animals,

and those people were therefore not created in God’s image. This meant that nonwhites were inferior and did not deserve equal consideration. Although these explanations for the origins of racial differences were common in the nineteenth and early twentieth centuries, by the mid-1900s they were largely abandoned.

The most easily identifiable form of racism in American history has existed between European Americans and African Americans. Not only did the institution of slavery further racist assumptions that people of African descent were inherently different and inferior, but racism toward blacks also continued long after emancipation. Well into the twentieth century there were laws in the United States that limited the rights of African Americans. These restrictions became known as Jim Crow laws after the popular nineteenth-century song “Jump Jim Crow,” which was performed by whites in blackface and stereotyped African Americans. Jim Crow laws were state ordinances that required whites and blacks to remain segregated in public places, and in many parts of the country schools, restaurants, restrooms, and public transportation remained segregated until the 1960s.

Although American racism is most closely associated with white-black prejudice, other groups have also been affected. For instance, Jews have long been discriminated against in American society. Although some argue that this treatment was a result of religious differences, many Americans have considered Jews a distinct race and have therefore thought of them in racialized terms. Beginning in colonial America, Jews were generally barred from holding public office and voting. Stereotypes that Jews were dishonest, greedy, and immoral have been common in the United States since the colonial period. For example, in 1862 General Ulysses S. Grant issued an order expelling all Jews from Kentucky, Tennessee, and Mississippi over concern that they were involved in dishonest economic activities. Social Darwinism also affected American Jews and led to an increase in anti-Semitism in the nineteenth century.

Asian Americans have also been the victims of racism, especially in the American West. In the nineteenth century Chinese immigration to the United States increased as a result of the gold

rush and as jobs with railroads became available. During this time a number of state laws and local ordinances were put into place that discriminated against the Chinese. For example, mid-nineteenth-century California laws forbade Chinese immigrants from testifying against European Americans, denied them the right to marry whites, required them to pay special taxes, and refused to grant them citizenship. During this time there were also attempts to drive Chinese Americans out of California, Oregon, Washington, Wyoming, Nevada, and Colorado. In 1875 the federal government also became involved in passing the Page Act, which barred nearly all Asian women from immigrating to the United States, and the 1882 Chinese Exclusion Act and its renewals suspended Chinese immigration until well into the twentieth century.

Late-Nineteenth-Century Irrationalism

Philosophical irrationalism is the belief that emotion, instinct, will, or faith, but not reason, is and should be the final determiner of truth, meaning, and reality. It claims that the universe is essentially without reason, that paradox and contradiction characterize reality, and that existence may even be absurd. Extreme forms of irrationalism hold that there is no truth, meaning, or reality. Nineteenth-century irrationalists, through their general pessimism, were forerunners of twentieth-century existentialism.

The fountainhead of late-nineteenth-century irrationalism was German pessimist philosopher Arthur Schopenhauer (1788–1860). However, its roots can also be traced to the first Christian existentialist, Danish theologian Søren Kierkegaard (1813–1855); German Romantics such as Friedrich Schlegel (1772–1829), Friedrich Daniel Ernst Schleiermacher (1768–1834), and Friedrich Wilhelm Joseph von Schelling (1775–1854); and German critics of the Enlightenment such as Johann Georg Hamann (1730–1788) and Friedrich Heinrich Jacobi (1743–1819). Schopenhauer remained mostly unknown until the last decade of his life but became one of the most celebrated Western philosophers from about 1860 until the third decade of the twentieth century. His influence extended not just to philosophy but also to literature, art, music, general intellectual life, and even popular culture.

German irrationalist philosopher Eduard von Hartmann (1842–1906) created a peculiar synthesis of absolute idealism and Schopenhauerian voluntarism that he published in several works, beginning with his 1869 *Philosophy of the Unconscious*. Schopenhauer, who strongly opposed absolute idealism and personally detested its main exponent, Georg Wilhelm Friedrich Hegel (1770–1831), would have been appalled at any attempt to unite his philosophy of the blind will with any kind of rationalism, especially Hegel's. Nevertheless, von Hartmann's work proved influential, notably on the psychoanalytic theories of Viennese neurologist Sigmund Freud (1856–1939) and Swiss physician and philosopher Carl Gustav Jung (1875–1961).

Arthur Schopenhauer is one of the most acclaimed philosophers of the nineteenth century. He rejected the rationalism of Kant and Hegel and argued that human behavior is motivated by the individual's basic desires, or will. He took a pessimistic view of existence, concluding that individual physical and emotional desires can never be fulfilled. (Bettmann/Corbis)

The major irrationalist of this era was French philosopher Henri Bergson (1859–1941), who eschewed analysis, rejected dualistic subject/object epistemology, and claimed instead that knowledge is possible only through an intuition of the duration of an object. The intuited object disappears into the knower's feeling of it so that the duality of knower and known is overcome, and the knowledge thus gained is deeper and richer than if the object had remained a traditional object for a subject. Bergson's influence on philosophy has been sporadic, but his influence on art and literature has remained steady and profound.

Irrationalism had immediate ramifications in literature, drama, poetry, and art. Norwegian Henrik Ibsen (1828–1906) wrote wild, poignant dramas of realistic psychological conflict. Influenced by Ibsen, Swedish dramatist August Strindberg (1849–1912) loaded his plays with neurotic, pessimistic, and hauntingly incongruous themes. Irish playwright Oscar Wilde (1854–1900) also found inspiration in Ibsen. Alfred Jarry (1873–1907), the first absurdist playwright, premiered his *Ubu Roi* (King Turd) in 1896. This play, full of puns and obscenities, satirized William Shakespeare and depicted a foul old man bent on conquering Poland. Novelists who were informed by Schopenhauer's pessimism included Thomas Hardy (1840–1928) and Lev Tolstoy (1828–1910).

English illustrator Aubrey Beardsley (1872–1898) championed the art nouveau movement and its philosophical counterpart, aestheticism, that extolled meaningless beauty over beautiful meaning. Other prominent aestheticists were Wilde, English critic Walter Pater (1839–1894), and American expatriate painter James Abbott McNeill Whistler (1834–1903). Aestheticist attitudes also appeared in France, in the poetry of decadents such as Charles Baudelaire (1821–1867) and symbolists such as Stéphane Mallarmé (1842–1898), who were each influenced by American poet, mystery writer, and critic Edgar Allan Poe (1809–1849). Aestheticism was also evident in the postimpressionist painting of Paul Cézanne (1839–1906). Mallarmé and Cézanne influenced the spiritual poetry of Rainer Maria Rilke (1875–1926).

—Eric v.d. Luft

➤ NIETZSCHE AN IRRATIONALIST?

Many interpreters of the philosophy of Friedrich Nietzsche (1844–1900), especially his detractors, label him an irrationalist. This interpretation does not withstand scrutiny, since reason plays an important and productive role in Nietzsche's thought. While Schopenhauer's influence on Nietzsche in the 1860s and 1870s cannot be denied, Nietzsche outgrew pessimism in the 1880s to develop a program for using both reason and emotion to build toward the high cultural creativity of the world historical future. Where Nietzsche seems to attack reason, his target is not reason as such but rather the misuse of reason for acquisitive, ignoble, or nonartistic ends. He was particularly harsh on the reason that enslaves people, exalts militarism, or promotes base values.

Freud and Freudianism

Sigmund Freud's impact on modern thought and culture is difficult to overemphasize. He is most famous for founding the theories and methods of psychoanalysis, which revolutionized modern conceptions of consciousness, therapy, and culture. He investigated the psychological mechanisms of the unconscious mind, focusing on sexual desires as a central, though repressed, source of human motivation, a common contemporary assumption that was popularized in part through his work.

Freud was born in 1856 in Freiburg, Moravia, then part of the Austrian empire, and moved

with his parents to Vienna at age four. After receiving a medical degree from Vienna University, in 1881 he began work at the Vienna General Hospital and in 1885 was appointed as a university lecturer in neuropathology. With the help of Wilhelm Fliess, Freud experimented in the clinical uses of electroshock therapy, hypnosis, and cocaine, with sometimes disastrous results. Joseph Breuer and Freud published together on the subject of hysteria and trauma. Using free association, a technique that Freud developed, he also began to treat patients for neurosis, that is, the patients' unconscious and unresolved conflicts manifested as emotional or physical disturbances. This formed the kernel of the theories and practices that he would call psychoanalysis.

Freud achieved the fame he sought with his landmark publication, in 1900, of *The Interpretation of Dreams*, in which he argued that the unconscious mind is driven by often-contradictory libidinal desires limited by the constraints of one's conscious everyday life. He argued that with free association, it was possible to help patients uncover these latent dream desires and that this in turn would enable them to understand the causes of their neuroses. He insisted that these neuroses were produced during specific conflicts in an individual's infancy and youth. After the publication of *The Interpretation of Dreams*, Freud became increasingly explicit in how his theories applied not only to neurotics but also to supposedly well-adjusted people, a distinction that he both drew and blurred in his writings. Fame and controversy followed the rest of his life's work.

In 1908, along with Alfred Adler and Carl Jung, Freud organized the first International Congress of Psychoanalysis in Salzburg, Austria. A lecture series that Freud and Jung gave in the United States in 1909 added to Freud's rapidly growing international reputation. Among the early psychoanalysts of the Vienna Psychoanalytic Society, arguments led to expulsions, and expulsions led to polemics: Adler started his own school of psychoanalysis in 1911, and Jung followed suit in 1914.

Freud was versed in classical and modern works of literature, art, science, and philosophy. His interest in anthropology led to his analysis of so-called primitive cultures in *Totem and Taboo*

(1913). He turned his attention again to culture and religion with works such as *Civilization and Its Discontents* (1930) and *Moses and Monotheism* (1939). Despite his own professed atheism, political anti-Semitism continued to constrain his life and, for some, define his works: in 1933 Hitler came to power in Germany, and Freud's books were among those burned in Nazi bonfires. With the German annexation of Austria in 1938, Freud fled to London, where he would remain until his death in 1939, finally succumbing to excruciating cancers of the mouth and jaw.

Freud's theories of psychoanalysis developed and changed over time. His initial writing on dream analysis argued that the mind is driven by libidinal desires, but the self attempts to suppress their manifestation in everyday waking life. Just as a censor acts to distort information in a closed society, an individual's unconscious mind censors and displaces the latent meaning of a dream into the less objectionable manifest content remembered and reconstructed upon waking. One's repressed wishes are nonetheless decipherable, if encrypted, in one's dreams. The goal of psychoanalysis was to work with the patient backwards, through this manifest dream content, with the free associations of the patient until the hidden latent meaning was revealed.

Freud is most famous for his analysis of the self, comprised of forces known as the Ego, the Super-Ego, and the Id. The Ego attempts to realize one's desires through acceptable social norms. Thus, one's desire for sex can be sublimated, or transformed, into other more socially acceptable creative and generative acts; one's death drive can likewise be sublimated into less violent pursuits. The Super-Ego is the internalization of social norms and controls that become an integral part of the individual; its censoring demands are negotiated by the Ego. The Id is the locus of libidinal desires, for sex and violence, creation and death, which is constantly demanding satiety. Libidinal energies are shaped and focused during an individual's early life by particular challenges faced in different stages of childhood development. For example, in the phallic stage, the male child negotiates the sexual desire he feels for his mother with his fear of castration at the hands of his father, known as the Oedipus complex. Women, he

added, have their own corresponding Elektra complex. Freud's stages of development assume a hierarchy of normality and deviance depending on their successful resolution by a maturing individual.

Freud also wrote about culture and society. He analyzed the works of artists like Feodor Dostoevsky and Leonardo da Vinci. Ancient and modern civilizations were the subjects of *Totem and Taboo* and *Civilization and Its Discontents*, respectively. In the latter work, Freud examined a seemingly intractable problem of modern society: the more developed the civilization, the more repressed an individual's desires will be in order to conform. In other words, civilization itself becomes neurotic in time, as the sex and death drives of individuals' libidos are increasingly constrained by social mores.

Though many of Freud's theories have fallen into disrepute, his analytic approaches are still widely influential and have been internalized in both academic and popular culture. Some feminists and other contemporary theorists, reworking a number of his gendered and cultural assumptions, continue to use his work productively.

Beginnings of Anthropology

Anthropology is the comparative science of the social behavior, physical characteristics, environmental relations, and geographic origins of either humans in general or humans in cultures other than that of the scientist. When scientists study only their own culture in this way, they are usually doing sociology.

Three major types of anthropology emerged in the late eighteenth and early nineteenth centuries. Physical or biological anthropology studies the quantifiable facts of human types relative to one another. It began as racial classification

and anthropometry but expanded to include evolutionary theory, ecology, medical anthropology, and genetics. Cultural or social anthropology describes and evaluates what humans have established as various societies, ethnicities, religions, customs, and institutions and includes ethnography, archaeology, and linguistics. Philosophical anthropology, as practiced by the German philosophers Immanuel Kant (1724–1804) and Johann Gottfried von Herder (1744–1803), is the speculative science of how rational humans would likely behave in various moral, social, religious, or political dilemmas.

Anthropology began in the wake of Swedish botanist Carolus Linnaeus's (1707–1778) developing an adequate classification system for plants. The impetus grew to apply the Linnaean system to other living things, including humans. Influenced by Linnaeus and the human bone measurements of Dutch comparative anatomist Petrus Camper (1722–1789), the German physician Johann Friedrich Blumenbach (1752–1840) founded physical anthropology in the 1770s.

Cultural anthropology arose in response to the European intelligentsia's newfound curiosity about African, Asian, and Native American cultures, particularly their religions and mythologies. The first cultural anthropologists did

➤ ANTHROPOLOGY AND RELIGION

The anthropology of religion, an essential aspect of cultural anthropology, started slowly in the early nineteenth century with German and British translations of sacred Hindu and Buddhist texts. It began in earnest when the literal truth of the Bible was first seriously challenged, in a series of *Encyclopaedia Britannica* articles in the 1870s by Scottish scholar William Robertson Smith (1846–1894). Smith's *The Religion of the Semites* (1889), along with *The Legends of Genesis* (1901) by German professor of Old Testament studies Hermann Gunkel (1862–1932) and *The Elementary Forms of Religious Life* (1912) by French sociologist Émile Durkheim (1858–1917), established that scholars could study the Judeo-Christian tradition objectively on a par with the religious traditions of other cultures.

—Eric v.d. Luft

not themselves travel into the lands they studied but instead depended on information brought back by missionaries, soldiers, sailors, explorers, and merchants. Thus nineteenth-century anthropology was generally tainted by the condescending attitude of the conqueror. This problem was not remedied until the American anthropologist Margaret Mead (1901–1978) visited Samoa in the 1920s.

An important task of cultural anthropology is to record stories, especially oral tradition. The German brothers Jakob (1785–1863) and Wilhelm Grimm (1786–1859) collected and published northern European folklore. The American bank clerk Thomas Bulfinch (1796–1867) compiled popular collections of Western mythology in his spare time.

The founder of modern systematic cultural anthropology was Oxford University Museum curator Edward Burnett Tylor (1832–1917). Three of his books, *Researches into the Early History of Mankind* (1865), *Primitive Culture* (1871), and *Anthropology* (1881) remain standards in the field. Scottish anthropologist James George Frazer (1854–1941) contributed *The Golden Bough: A Study in Magic and Religion* (1890). Classic works such as *Totem and Taboo* (1913) by the Viennese psychoanalyst Sigmund Freud (1856–1939) and *The Rites of Passage* (1908) by the Dutch anthropologist Arnold van Gennep (1873–1957) relied on the groundwork laid by Tylor and Frazer.

Origins of Sociology

Sociology is the scientific study of society, especially the social behavior and relations evident in one's own culture. Sociology emerged from cultural anthropology, specifically through the realization that the same observational, metric,

and analytic techniques by which scientists studied other cultures could also be used to study their own.

The French positivist philosopher Auguste Comte (1798–1857) founded sociology in the 1830s and coined the term in 1839 in his *Course of Positive Philosophy*, which appeared in six volumes from 1830 to 1842. By the 1850s both the philosophy of positivism and its offspring, the science of sociology, were well established in European intellectual circles. Comte's main thesis was that social relationships and structures are determined by natural law. This idea is corollary to positivism's central claim that natural science should govern both philosophy and social theory because humanity is ultimately subject to natural law. Not all subsequent sociological theory was positivist, and since the early twentieth century Comte has been more a figure of historical interest than a viable thinker in the continuing sociological conversation.

The English philosopher Harriet Martineau (1802–1876) translated Comte into English in 1853. Several of her books, especially *Society in America* (1837), are precursors of sociological thought and added substantially to the political, economic, and sociological analysis of women and marriage. Despite Martineau's work, Herbert Spencer (1820–1903), who wrote many popular books and articles on sociology from the 1870s to the 1890s, is considered to be the founder of sociology in Britain. Both Martineau and Spencer drew heavily from the political and economic theory of Thomas Malthus (1766–1834).

The German philosopher Georg Wilhelm Friedrich Hegel (1770–1831) can be regarded as the godfather of sociology. Despite Comte's misunderstanding of Hegel and despite Hegel's aversion to positivism, Hegel had strong influence on most other early European sociologists. Hegel believed that humanity is best understood in terms of its ever-changing spiritual progress through distinct but dialectically related historical phases. Georg Simmel (1858–1918), rejecting empiricists such as Spencer, preferred to follow Hegelian dialectical lines of sociological reasoning. Another Hegelian, Karl Marx (1818–1883), best known as a philosopher of economics and politics, also made significant contributions to sociology.

A brilliant mathematician, Auguste Comte participated in the scientific intellectualism of the nineteenth century. He is best known for developing the philosophy of positivism and as the founder of sociology. (Library of Congress)

German sociologists, each with a keen knowledge of Hegelian thought, originated many of the basic concepts of sociology. Wilhelm Dilthey (1833–1911) eschewed Comte’s positivistic approach to sociology and instead developed *Geisteswissenschaft* (cultural science), which used psychology, philosophy, art history, and many other disciplines to gain a broad understanding of the human spirit and its progress. In 1887 Ferdinand Tönnies (1855–1936) introduced the contrasting ideas of *Gemeinschaft* (community), an organization that expects its members to surrender their individuality to the group, and *Gesellschaft* (society), a free association of individuals who retain their individuality as members of the group. These German terms have entered the standard English sociological vocabulary.

In France, Émile Durkheim (1858–1917) studied social integration and introduced to sociology the idea of anomie, the breakdown of society. His most noteworthy books are *The Division of Labor in Society* (1893), *The Rules of Sociological Method* (1895), *Suicide* (1897), and *The Elementary Forms of Religious Life* (1912). Durkheim is credited with making sociology a genuine science.

The Study of History

Historiography, the writing of history, changed little from the time of Herodotus and Thucydides, the fifth-century BCE Greek inventors of this discipline, until the end of the eighteenth century. It was mostly just storytelling with little academic rigor. Even the most famous historical work of the eighteenth century, *The Decline and Fall of the Roman Empire* by Edward Gibbon (1737–1794), belongs to this narrative genre despite its speculative interpretation of the rise of Christianity.

The impetus for developing history into a scholarly discipline came mainly from the Germans, notably philosophers Johann Gottfried von Herder (1744–1803), Wilhelm von Humboldt (1767–1835), and Georg Wilhelm Friedrich Hegel (1770–1831). Herder’s speculations on the origins of cultural phenomena began to lead history away from narrative and toward analysis. His *Ideas toward the Philosophy of Human History*, which appeared in four parts from 1784 to 1791, proved to be tremendously influential. Humboldt advocated documenting underlying historical ideas as well as overt historical facts. Hegel detected in the natural course of events a rationality and a logic that made history a dialectical science. His dictum that what is real is rational influenced his fellow professor at the University of Berlin, Leopold von Ranke (1795–1886), the world’s first professional systematic historian. Ranke was not a Hegelian but absorbed enough Hegelianism to try in his books to provide an overarching reason for the succession of historical events.

Among von Ranke’s critics was his student Jacob Burckhardt (1818–1897), who believed that von Ranke saw history too much in terms of the actions of the upper classes. Burckhardt founded *Kulturgeschichte* (“history of culture”), which studied broad movements such as industrialization, nationalism, mercantilism, and individualism. In contrast to von Ranke’s conservative optimism, Burckhardt’s interpretation of European history was starkly pessimistic and

► THOMAS CARLYLE AND HISTORY

The most famous historian in the nineteenth century was Thomas Carlyle (1795–1881), a Scottish author. His frankly subjective, pro-British interpretation of the French Revolution became very popular, colored further interpretations, and largely prevented more objective assessments until the middle of the twentieth century. Along with his friend and correspondent of 50 years, American essayist Ralph Waldo Emerson (1803–1882), Carlyle argued that history is nothing but biography, or a concatenation of biographies, and that world historical events are nothing but the actions of “great men.” In so doing, they exploited the German concept of *Lebensgeschichte* (“life history”).

—Eric v.d. Luft

often chillingly accurate in predicting wars and social upheavals.

Much of the technical historiographical vocabulary has come into English from untranslatable German terms coined in the nineteenth century. *Heilsgeschichte* (“salvation history”) denotes the interpretation of events through the lens of Christian theology. *Geistesgeschichte* (“history of spirit”) refers to historical methods characterized by highly interpretative, psychological, or even romantic approaches. Wilhelm Dilthey (1833–1911) was interested in ascertaining what constitutes valid historical knowledge and how it may be acquired. His method of *Geisteswissenschaft* (“science of the spirit”) attempted to understand human culture by investigating its psychological, emotional, artis-

tic, and philosophical causes rather than just its political, economic, or military factors.

The new historiography was not without ulterior motives. English politician Thomas Babington Macaulay (1800–1859) wrote a five-volume history of England to suit his Whig Party. Wilhelm von Giesebrecht (1814–1889), another student of von Ranke, wrote a six-volume history of medieval Germany that was explicitly designed to inspire patriotism. By contrast, German legal scholar Theodor Mommsen (1817–1903) wrote a history of ancient Rome that encouraged readers to distrust nationalism, state power, and central authority.

In the second half of the nineteenth century German historiographical methods dominated academia throughout the West. Gabriel Monod (1844–1912) brought these methods to France and in 1876 founded *Revue Historique*. Herbert Baxter Adams (1850–1901), cofounder of the American Historical Association in 1884, made Johns Hopkins University the center of American historiography in the late nineteenth and early twentieth centuries.

Science and Technology

As much as any political revolution, economic change, or social transformation, developments in technology and science were a driving force in human history between 1750 and 1914. Scientific discoveries provided new answers to age-old questions about the nature of matter, the causes of disease, the age of the earth, the origins of humankind, and the properties of heat, electricity, and light. So spectacular were its findings and so certain were its methods that by the late 1800s, science seemed capable of creating a future in which mystery and human misery would both disappear. Technological innovation had an even greater impact. It initiated and drove the process of industrialization, transformed communications and travel, created new wealth and weapons, and affected even the most mundane aspects of everyday life. These scientific and technological advances took place almost exclusively in Europe and the United States, and taken together, they largely explain the rise of Western global dominance in the nineteenth century.

Europe had a strong scientific tradition well before the eighteenth and nineteenth centuries. In the Middle Ages and the Renaissance, university professors and their students pored over the works of Aristotle, Galen, Ptolemy, and other ancient Greek thinkers to better understand the natural world and the God who created it. In the sixteenth and seventeenth centuries, the era of the Scientific Revolution, the heritage of ancient science was rejected by learned men who offered new insights into the earth's place in the universe, the movements of planets and stars, the nature of terrestrial motion, optics, anatomy, and the circulation of the blood. Published in 1687, Isaac Newton's *The Mathematical Principles of Natural Philosophy*, in which he demonstrated the law of universal gravitation, was a monument to the powers of human reason and an inspiration for the hopes and dreams of writers who contributed to the eighteenth-century Age of Enlightenment.

Europe also had a long tradition of technological innovation. In the Middle Ages, drawing on Roman antecedents and borrowing from Asia, Europeans adopted gunpowder and the astrolabe; invented eyeglasses, mechanical clocks, the blast furnace, vertical windmills, buttons, the hourglass, and the mirror; and improved water mills, construction methods, farming techniques, and ship design. The Renaissance fostered refinements in shipbuilding, the making of gunpowder weapons, and the techniques for paper making and printing, and the era of the Scientific Revolution saw the invention of the telescope and microscope. The theoretical speculations of university-trained scientists had little to do with these technological advances, which were the work

of craftsmen and tinkerers with little or no advanced academic training. Even the discoveries of the Scientific Revolution had no practical effects. The knowledge that the earth orbited the sun and that planets moved in elliptical, not circular, orbits did not improve navigational techniques; the discovery of the circulation of the blood by William Harvey (1578–1657) did not improve medical practice; and the investigation of the properties of magnets by William Gilbert (1544–1603) had no practical applications.

The separation between the worlds of the inventor and the scientist continued in the first century of Europe's industrialization. Abraham Darby (1678–1717), a farmer's son who developed a method for producing high-grade iron in a blast furnace fueled by coke (scorched coal) rather than charcoal (scorched wood), was a maker of iron pots. Henry Cort (1740–1800), who invented the puddling process for refining pig iron, was an ironmaster. Neither man drew on scientific theory to make his invention, yet their work revolutionized iron production. Of the men whose inventions revolutionized the textiles industry in the eighteenth century, John Kay (the inventor of the flying shuttle) was a manufacturer of parts for handlooms; Richard Arkwright (the inventor of the water frame) was a wigmaker turned entrepreneur; James Hargreaves (the inventor of the spinning jenny) was a weaver and carpenter; and another John Kay (who helped Arkwright in the development of the water frame) was a clockmaker. The steam engine, the most important single invention of the age, resulted from the work of Thomas Newcomen, an ironmonger and lay preacher, and James Watt, an instrument maker. Although Watt plied his trade at the University of Glasgow and was honored with memberships in several

Although Watt plied his trade at the University of Glasgow and was honored with memberships in several scientific societies, he had no scientific training, and even if he had, it would have taught him nothing that he could have applied to his work.

scientific societies, he had no scientific training, and even if he had, it would have taught him nothing that he could have applied to his work. The first scientific study of steam engines, Sadi Carnot's *Reflections on the Motive Power of Heat*, was published only in 1824, when thousands of steam engines already were in operation worldwide. Only in the mid-nineteenth century did scientific theory begin to advance technology, a process that accelerated as the century drew to a close.

Many factors contributed to scientific progress and the attendant acceleration of technological development in the nineteenth century. Most importantly, the field of science was redefined and expanded. In addition to astronomy, mechanics, mathematics, and optics, which had been the focus of scientific inquiry since antiquity, there developed a number of "new" sciences, including meteorology, geology, chemistry, and the study of electricity, heat, and magnetism. Older subjects of inquiry were redefined. The term "biology," for example, first used in 1802, came to be applied to the laboratory-based and experimental approach to investigating the chemistry and physiology of plants and animals. A new understanding of physics also emerged. The term "physics"

came to mean the study of matter and energy and their interactions, with subfields of astronomy, mechanics, optics, acoustics, electricity, magnetism, and radiation. Chemistry received a new nomenclature, theoretical basis, and methodology through the work of Joseph Black (1728–1799) on chemical reactions and the nature of carbon dioxide, Joseph Priestley (1733–1804) on oxygen and other gases, and Antoine Lavoisier (1743–1794), who stated the first version of the law of conservation of mass, recognized and named oxygen and hydrogen, explained combustion, helped devise the metric system, and drew up the first extensive list of elements. By midcentury the term “scientist,” coined in 1840, entered common parlance as referring to a trained professional dedicated to the study of nature through observation and experiment.

The professionalization of science changed how science was organized and taught. Traditional learned societies such as the Royal Society of London and the French Academy of Sciences, which drew their memberships from accomplished individuals in all branches of science, continued to exist, but they lost their role as a primary vehicle for the presentation of research. This role instead was assumed by organizations specializing in astronomy, geology, chemistry, mathematics, and other subdisciplines. Specialized journals also proliferated.

Important changes also took place in the teaching of science and the emerging new profession of engineering in schools and universities. Beginning in the eighteenth century, the French monarchy underwrote the founding of specialized academies, separate from the country’s several universities, dedicated to training select students in engineering (a word derived from the Latin root *ingeniare*, “to devise”). They included the École nationale des ponts et chaussées (National School of Bridges and Roads), founded in 1747; the École Nationale Supérieure des Mines (Advanced National School of Mines), founded in 1780; and the École centrale des travaux publics (Central School for Public Works), founded in 1794 and renamed the École Polytechnique one year later. The latter served as a model for numerous technical schools in the United States and Europe.

During the 1800s science attained a place in the curricula of German universities, where original research, not the transmission of inherited knowledge, became the focus. A key figure was Justus von Liebig (1803–1873), whose much-imitated program for training chemists at the University of Giessen included laboratory work, original research, seminars, and colloquia. The model of the research university spread to England, where Oxford, Cambridge, and the newly founded University of Manchester built laboratories and introduced a rigorous scientific curriculum; it also took hold in the United States, where graduate programs proliferated from the late 1870s onward. Important scientific and technical research also took place in large urban hospitals and the industrial research laboratories that many businesses sponsored beginning in the late 1800s.

It would take many pages to describe the astounding results of nineteenth-century science and the many ways that science transformed technology and industry. Among them, several stand out. Research

conducted on current electricity between the 1780s and the 1840s gave rise to the telegraph, the telephone, electric lights, household appliances, and a totally new industry dedicated to the generation of electricity. The emergence of chemistry resulted in new materials, dyes, fertilizers, and pharmaceuticals; it also led to new methods for producing steel and gunpowder, processing food, and refining petroleum. The theoretical work of James Maxwell (1831–1879) on electromagnetic waves led to the development of the wireless by Heinrich Hertz (1857–1894) and the discovery of X-rays by Wilhelm Roentgen (1845–1923). The growth of applied science went beyond physics and chemistry. In medicine, the introduction of anesthesia in dentistry and surgery

in the 1840s and the development of antiseptic measures in the 1870s both had untold benefits. So too did the discovery of the role of bacteria in causing disease, which made possible the development of vaccines for the prevention of anthrax, rabies, and other diseases.

By the end of the nineteenth century science had become part of popular culture in Europe and the United States. Botanical gardens and zoos as well as museums of science and natural history proliferated.

By the end of the nineteenth century science had become part of popular culture in Europe and the United States. Botanical gardens and zoos as well as museums of science and natural history proliferated.

Botanical gardens and zoos as well as museums of science and natural history proliferated. “Scientists” were frequently featured in print advertisements to testify about the purity and benefits of products ranging from chocolate to patent medicines. Beginning in the early 1900s, children from middle-class families received science kits and toy microscopes as gifts.

Science and technology not only changed how people lived but also changed how people thought. For most Europeans and Americans the new discoveries and inventions encouraged their belief in progress and the superiority of Western civilization. Discoveries about the age of the earth and Darwin’s theories of evolution disturbed many religious persons because they seemed to contradict the biblical account of creation. On the other hand, Darwin’s ideas of the “struggle for existence” and the “survival of the fittest” were used by others to justify imperialism, militarism, laissez-faire capitalism, nationalism, and the disparity between the rich, who had proved themselves “fit” in the struggle for existence, and the weak and feckless poor.

As European economic influence and political power spread across the globe, so too did its new technologies. Railroads traversed Siberia, crisscrossed India, and linked Africa’s interior to the coast. Telegraph lines were strung across land and ocean floors to connect every continent but Antarctica. Irrigation projects were undertaken in India, and the Suez Canal was constructed to link the Mediterranean Sea and the Indian Ocean by way of the Red Sea. All of these projects were designed and overseen by European engineers and used machines and materials produced in European factories. Asia, Latin America, and Africa also attracted the interests of European scientists. With research subsidized by scientific societies and governments, scientists collected botanical specimens, observed animal life, prepared maps, investigated

geological structures, and published their findings in scholarly journals. More importantly, Western engineering skills and scientific knowledge gradually were imparted to small numbers of non-Europeans.

Interest in Western science and technology in other parts of the world predates the nineteenth century. As early as the 1400s, Asian rulers employed European experts to teach the skills of manufacturing artillery and guns. Beginning in the late sixteenth century, Chinese emperors welcomed Jesuit missionaries to the imperial court, where they served as astronomers, mapmakers, mathematicians, and teachers of clock making, surveying, and glass making. Even after the Kangxi emperor prohibited missionary work in 1717, a few Jesuits and ex-Jesuits continued to be employed at the imperial court. In Japan, even during its period of isolation, Dutch merchants were required to report annually to the shogun in Edo on recent political and scientific developments in Europe, and in the eighteenth century small numbers of Japanese studied Western science, especially anatomy, after the ban on importing Western books was lifted after 1720.

In the nineteenth century the diffusion of Western science, technology, and technical know-how accelerated. Political leaders of independent states in Asia and Latin America all made efforts to provide opportunities for technical and scientific training to close the economic and military gap between their countries and the West. Japan was notably successful in these efforts. By the early 1900s, it had four universities with programs in science, medicine, and engineering, all taught by Japanese professors rather than imported European scholars. The government also supported agricultural experiment stations, the Industrial Experiment Laboratory, the Electrochemical Laboratory, the Railways Research Institute, and a number of colleges and other institutes for the study and teaching of veterinary science, forestry, sericulture, and meteorology. The government also funded foreign study (for almost 3,000 students between 1888 and 1912) and several scientific societies and scientific journals.

Elsewhere, however, political uncertainty, financial constraints, intellectual inertia, and religious opposition hindered scientific progress. In China, where Protestant missionaries had promoted the study of Western science and medicine beginning in the 1840s, the Qing government did not fully commit itself to a program of scientific and technical training until after China's defeat by Japan in the Sino-Japanese War of 1895. The government then outlined a broad program for educational reform but had just begun to implement it when the government was overthrown in the Revolution of 1911. Between 1898 and 1911 only 200 students graduated with scientific degrees from the newly founded Imperial University in Beijing.

In the Middle East, the ambitious plans of Muhammad Ali, the ruler of Egypt from 1805 to 1849, to promote Western science and engineering through foreign study, a government-sponsored translation program, and new schools lost momentum after his death in 1849 and the establishment of the British protectorate in 1882. In Persia and the Ottoman empire, government schools to train military personnel in medicine and engineering were founded in the early 1800s, and efforts were

made to establish European-style universities. Persia's Dar al-Funun, founded in 1851 with a faculty of Europeans and European-educated Persians, offered instruction in foreign languages, mathematics, and the sciences, but it was poorly funded and attracted small numbers of students. Plans to found a similar institution in Istanbul were first made by Ottoman officials in the 1840s, but after three failed attempts, instruction began only in 1900. In the empire's Arab provinces, two missionary schools, the Syrian Protestant College and St. Joseph's University, both founded in 1866 in Beirut, made important contributions to the teaching of Western science and medicine. By 1900 the number of graduates in medical and scientific fields at the two institutions numbered around 2,000.

In the colonized areas of Asia and Africa, the diffusion of Western science, medicine, and engineering varied widely. At one extreme was India, where the British sponsored schools, colleges, and universities at which science, medicine and engineering were taught. They also subsidized museums and botanical gardens and underwrote scientific societies. For the British, promoting science had the benefits of spreading the benefits of Western civilization, affirming the superiority of Western learning to that of India, and, most importantly, helping Britain administer its giant colony by educating Indians for jobs in the Indian Medical Service and the Indian Civil Service. All of these efforts were well received by the Hindu population and attracted significant financial support from Indian princes, landowners, and industrialists. In fact, from 1878 onward, in Bengal private aid to education, including scientific education, exceeded the amount provided by the government.

Outside of India, colonial powers did little to encourage education, let alone advanced education in science and engineering. Paradoxically, one of the reasons was to avoid what had developed in India, which by the end of the nineteenth century had a sizable and vocal number of educated natives dissatisfied with their vocational prospects and critical of India's colonial status. This was behind the thinking of Sir Frank Swettenham, governor of Britain's Federated Malay States, who wrote in the 1890s that "Whilst we teach children to read and write and count in their own languages . . . we are *safe*. Beyond that, I should like to see the boys taught useful industries and the girls weaving, embroidery, and mat-making." In Africa, education was left to missionaries, most of whom agreed that most Africans were incapable of grasping literary and scientific subjects. The instruction that the missionaries offered rarely went beyond religion, personal hygiene, arithmetic, and basic literacy. More educational opportunities were provided in the twentieth century, but it continued to be believed that Africans should be trained to become mechanics, carpenters, blacksmiths, and masons, not chemists or biologists. After independence, the shortage of engineers, scientists, and science teachers was one of many challenges faced by the new African states.

—James H. Overfield

■ Introduction: Technology and Industry

During the period 1750–1914, technology and industry deepened their connection with a vast number of inventions that increased productivity, sparked the first and second Industrial Revolutions, and developed worldwide trade to a level never seen before. Of course, technological developments were interwoven with other segments of society as well. The relationship between labor and capital underwent vast changes, spawning a host of economic, cultural, political, and social movements varying from trade unions to suffrage to utopianism and socialism. Steamships, telegraphs, and railroads shrunk distances, promoted regional specialization, and changed the course of how wars were fought. By 1914 a new industrial, technological, and urban world order was in place.

In textile manufacturing, the process of spinning raw materials into thread was aided by the invention of the spinning-jenny, the water frame, and the mule, while weaving was augmented by the flying shuttle and the power loom. The development of the steam engine and its application to steamboats, steamships, steam locomotives, and steam-operated industrial machinery transformed the world in ways unfathomed. So too did the inventions of the electric streetcar, the internal combustion engine, and, later, the automobile. Distance mattered less and less.

Industrialization also depended upon cheap and available supplies of energy. Coal, coke, electricity, and oil literally and figuratively ignited the world. Gas lighting, and later electric lighting, illuminated the night skies. The electromagnetic experiments of Michael Faraday, Thomas Edison, Oliver Lodge, Nikola Tesla, and Guglielmo Marconi led to such achievements as the first successful electric lightbulb as well as wireless communications. Fantastic electric displays fascinated crowds at many of the world's fairs of the time period. Visitors to international exhibitions marveled at new inventions such as the telegraph, the air brake, the telephone, and the wireless. World's fairs also celebrated technological feats of architecture, such as the Eiffel Tower of the 1889 Exposition Universelle in

Paris and the enormous Ferris Wheel at the 1893 Columbian Exposition in Chicago.

In steel production, the inventions of Henry Bessemer, Robert Mushet, Sydney Thomas, Percy Gilchrist, and Charles William Siemens improved both output and quality. In science, Joseph Priestley, Antoine Lavoisier, Charles Goodyear, Louis Pasteur, William Henry Perkin, Fritz Haber, and others laid the groundwork for advances in industrial chemistry. Academic and industrial research laboratories generated new innovations in hygienic products and fertilizers, improving the quality of life.

Literacy was enhanced by inventions in printing ranging from steam-powered cylinder presses to rotary presses to stereotypes. Typesetting was enhanced by linotype and monotype machines, and illustrations were enhanced by lithography, half-tones, and offset. Daily newspaper reading, featuring international news transmitted by transoceanic telegraph cables, became common among the growing middle class of the nineteenth century.

The middle class of industrial societies also had access to inventions that became increasingly affordable. These included the automobile. By 1914, when Henry Ford of the United States introduced a moving assembly line to manufacture his Model T automobiles, the groundwork was laid for further advances in industrial productivity.

—Paul Tenkotte

Innovations in Textile Manufacturing—Eighteenth Century

During the eighteenth century, a number of technological innovations initiated a period of revolutionary change in the history of textile manufacturing. The introduction of new machinery, first powered by water-driven engines and later by steam engines, radically modified the existing patterns of textile production and marked the passage from cottage industry to the factory system.

THE JACQUARD LOOM

The Jacquard loom, designed and patented in 1801 by Joseph Marie Jacquard, resulted from the modification and improvement of already-existing systems designed by Basile Bouchon, Jean Falcon, and, above all, Jacques de Vaucanson (also known for his ingenious automats). On the basis of Vaucanson's models, Jacquard designed an apparatus that greatly simplified the weaving of textiles with complex patterns. The machine's operations were controlled by punch cards. The punch cards in the Jacquard loom were pieces of paper containing digital information that was transmitted by patterns of holes. The presence or absence of holes on the paper conveyed to the mechanical apparatus the sequence of the pattern to be reproduced on the textile. In the silk-weaving industry the introduction of the Jacquard loom marked a new era. The Jacquard loom's use and dissemination in Europe, which took a couple of decades, simplified the weaving of richly decorated luxury textiles.

—Antonella Viola

These innovations first occurred in Great Britain. In 1733 John Kay patented the flying shuttle, which was attached to a loom and made possible the initial automation of the weaving process. In 1764 James Hargreaves invented a multispool spinning wheel, which was called the spinning jenny. This invention reduced the amount of labor needed for spinning. In the same year Richard Arkwright designed the so-called water frame, an improvement of the already-existing spinning frame that was unique in its employment of water to drive the spindles. A water wheel set the apparatus in motion, and the power generated by the wheel reduced labor and increased production. Samuel Crompton then developed new machinery that incorporated both the spinning jenny and the water frame. Like many other machines invented in that period, Crompton's muslin wheel, also known as the spinning mule, was initially utilized in the cotton industry, which also benefited from another new apparatus, the cotton gin. Specifically designed to separate cotton fibers from the seeds, the new machine,

patented by Eli Whitney in America, speeded up and simplified the cleaning process.

Although early innovations affected spinning, one of the main technical advances occurred in the weaving process when the first mechanized looms were introduced. The power loom was patented by Edmund Cartwright between 1784 and 1785. The power to move the loom was initially generated by water but soon came from steam.

The technological innovations that were first introduced in the cotton-manufacturing industry were gradually applied to other textiles. The silk industry, for instance, did not gain remarkable advantages from the improvements in spinning because silk is already a continuous filament that does not need to be spun (spinning occurred only in the production of silk waste). Therefore, the mechanization of the silk industry mainly involved the introduction of mechanical looms later in the nineteenth century. But in the eighteenth century the reeling process (the process of unwinding silk filaments from the cocoon) underwent significant modifications. By the turn of the century, there was a gradual introduction of steam power in the filatures (factories in which silk is reeled). The main innovations involved the mechanization of the rotation of the reeling frame. The use of a steam-driven machine allowed the operator to use both hands to reel silk thread. Steam was also employed to heat the basins in which silk cocoons were dipped for softening. In 1805 Ferdinand Gensoul patented the first steam-powered system to heat water in the basins and reel the silk threads. Furthermore, mechanization occurred in the twisting process with the introduction of a system that allowed the simultaneous intertwining of many silk threads while eliminating water. In this way silk's natural glue, sericin, made filaments stick to each other and form a single silk thread.

Most of the innovations in silk production occurred in countries other than Great Britain, which never had a tradition of sericulture but used to import raw silk to be manufactured domestically. Innovations in silk reeling led within a few decades to the establishment of fully mechanized filatures that used steam-powered machinery. Remarkable changes also occurred in the silk-weaving industry after the

introduction of mechanical looms. Joseph Marie Jacquard in 1801 invented a new mechanical loom that came to be known as the Jacquard loom. This innovation simplified the weaving process of those textiles that had complex patterns such as brocades or damasks. The Jacquard loom, which used programming cards to initiate different designs and as such was a forerunner of the modern computer, was soon extensively used in silk embroidery.

The growth of textile production in Western countries expanded the market for textiles, especially for cotton and silk. Moreover, the technical innovations in the textile industry had numerous socioeconomic consequences: Western textile industries became relatively more competitive, new supplies of raw materials were necessary, patterns of consumption began to change, and with changes in labor patterns, traditional modes of life were shattered. The technological innovations of the eighteenth century encouraged, in the following century, the definitive consolidation of the factory system and the spread of factories that replaced the system of the cottage industry.

Steel

Steel is an alloy of iron and carbon in its simplest form and has long been known as a superior tool and weapon metal. With a carbon content between 0.2 and 1.5 percent, it occupies a position between low-carbon wrought iron (.02 to

.08 percent) and high-carbon pig iron (3 to 4.5 percent). Until the nineteenth century the difficulty and expense of the manufacture of steel relegated it to limited use. During the latter half of the nineteenth century breakthroughs in manufacturing allowed the mass production of steel. Steel has since become a primary structural material.

Steel has been known since antiquity, but the processes used to manufacture it were expensive and inefficient. Before 1856 the primary methods of making steel were the cementation and crucible processes. The former involved layering bars of wrought iron and powdered charcoal in a stone box and heating it for several days. The resulting blister steel was broken up and run through the process again. It was then subjected to forging to create a more consistent texture. The crucible process was used to refine blister steel, melting it in clay crucibles with a special flux to remove minute bits of slag deposited during cementation. This process produced high-quality steel, but it was prohibitively expensive. As a result, steel was only used for small items and when nothing else would do.

Harper's Weekly illustration of the Bessemer steel process. English inventor Henry Bessemer's process for purifying low-quality iron made it possible to produce steel more cheaply and quickly. (Library of Congress)

➤ LIGHTING UP THE SKY

The following is a description of a Bessemer converter in action from *McClure's Magazine*, 1894.

“Out of each pot roared alternately a ferocious geyser of saffron and sapphire flame, streaked with deeper yellow. From it a light streamed—a light that flung violet shadows everywhere and made the gray outside rain a beautiful blue. A fountain of sparks arose, gorgeous as ten thousand rockets, and fell with a beautiful curve, like the petals of some enormous flower. Overhead the beams were glowing orange in a base of purple. The men were yellow where the light struck them, violet in shadow. . . . The pot began to burn with a whiter flame. Its fluttering, humming roar silenced all else. . . . A shout was heard, and a tall crane swung a gigantic ladle under the converting vessel, which then mysteriously up-ended, exploding like a cannon a prodigious discharge of star-like pieces of white-hot slag. . . . Down came the vessel, until out of it streamed the smooth flow of terribly beautiful molten metal. As it ran nearly empty and the ladle swung away, the dropping slag fell to the ground exploding, leaping viciously, and the scene became gorgeous beyond belief, with orange and red and green flame.”

Hamlin Garland, “Homestead and Its Perilous Trades—Impressions of a Visit.” *McClure's Magazine* 3, no. 1 (June, 1894): 14.

This changed in 1856 when Henry Bessemer patented a new process that used compressed air blasted through a crucible of molten pig iron. The oxygen in the air burned off the excess carbon in an operation described as volcanic in appearance. It was not perfect; initial batches had too little carbon and too much oxygen. This problem was solved by Robert Mushet, who discovered that adding a compound called spiegeleisen, an alloy of iron containing approximately 15 percent manganese and small quantities of carbon and silicon, after the initial blast

removed the excess oxygen and replaced the deficient carbon. The Bessemer converter was also incapable of processing iron made from high-phosphorus ores, a problem solved in 1878 by Sydney Thomas and Percy Gilchrist. They introduced a basic (as opposed to acid) liner and added lime as a flux to bond with the phosphorus. The resulting slag had the serendipitous quality of being a good fertilizer.

Despite the Bessemer converter's ability to produce tons of steel in a matter of minutes rather than days, there was room for improvement. The Siemens-Martin process was invented in 1868 by Charles William Siemens. Also called the Open Hearth process, it used a rectangular brick chamber heated by coke to melt a mix of pig and wrought iron along with a flux to carry off impurities as slag. Although it took considerably longer—7 to 12 hours as opposed to 30 minutes—it had several advantages. Quality could be controlled with a greater degree of precision and could be adjusted during the heating process. The Siemens-Martin process yielded a superior product and in the long run proved more efficient than the Bessemer converter. When combined with the Thomas-Gilchrist innovation the Siemens-Martin process became omnivorous, consuming iron-made low-grade and high-grade ores, scrap iron, and scrap steel. By 1904 it had become the dominant method of steel making on the European continent and in northern England, where high-phosphorus ore predominated.

The impact of cheap steel was tremendous, as exemplified by the effect on rail production. In 1867 the United States produced 460,000 tons of wrought iron rails that sold for \$83 per ton. In that same year 2,550 tons of Bessemer steel rails were manufactured, selling at up to \$170 per ton. By 1884 wrought iron rails had virtually disappeared from the market, replaced by 1.5 million tons of steel rails selling at \$32 per ton. By the end of the century Andrew Carnegie's factories were turning out steel rails for \$14 per ton. During that same period the average life of a rail went from two years for wrought iron to ten years for steel, and the weight that the rail could bear increased from 8 tons to 70 tons.

Industrial Chemistry

Industrial chemistry traces its beginnings to the 1740s with the emergence of gas chemistry, in which reactions began to be explained in terms of elements and atoms. Joseph Priestley (1733–1804), Carl Scheele (1742–1786), and Antoine Lavoisier (1743–1794) set the stage for the chemical revolution in the latter half of the nineteenth century with their initial steps to quantify chemical reactions and make chemistry a science. The subsequent coupling of the science of chemistry and business led to the need for the discipline of chemical engineering and the rise of chemical companies in the nineteenth century, many of which still exist today.

Chemical engineering appeared during the latter part of the eighteenth century in the form of dedicated chemistry classes, separate from their traditional pairing with the study of medicine. Journals in the late 1700s, such as the German *Chemisches Journal* (founded in 1778) and the French *Annales de chimie* (founded in 1789) also contributed to chemistry's growth as a scientific discipline. Then in 1845 the British established the Royal College of Chemistry to understand the chemical properties of materials just as the Industrial Revolution was creating a demand for compounds used in manufacturing. To this point dyes, soaps, perfumes, and medicines were produced by numerous craftsmen to satisfy local consumer demand for colored fabrics, cleanliness, luxuries, and health, respectively.

As small chemical shops with technicians gave way to a developing chemical industry in the nineteenth century, demand was created for engineers who possessed technical knowledge relating to chemical reactions, controls, and

Famous as the accidental inventor of the sulfur vulcanizing process for rubber, Charles Goodyear has had an incalculable impact on American society and the world in general. Goodyear improved natural rubber and it is now used in everything from automobile tires to paint to diving suits. (Hayward Cirker, and Blanche Cirker, eds. Dictionary of American Portraits, 1967)

processes and who could improve the efficiency of distillation, evaporation, absorption, and drying techniques. Chemical research laboratories were linked to the chemical companies during the nineteenth century and became more tightly linked as technological innovations were rapidly made with a scientific basis to bolster them. Germany took the lead in the competitive field of industrial chemistry for two reasons. First, the Germans developed an excellent system of scientific and engineering education. Second, German chemical companies established industrial research laboratories to complement established academic research labs.

There are many examples of how chemistry led to the development of new products in the nineteenth century. Joseph Priestley, better known for his work on gases, used a flexible material to erase or rub out pencil marks, hence the term “rubber.” Rubber also found practical uses as raincoats, or mackintoshes, and as wheels produced through Charles Goodyear's (1800–1860) process of vulcanization, which heats a mixture of rubber and sulfur. With the development of the automobile, the need for tires doubled the world's consumption of rubber at the beginning of the twentieth century. As rubber prices soared, manufacturers sought synthetic alternatives to the Malayan rubber tire. By World War I, acetone was being transformed to produce synthetic rubber and offset world demand for rubber hovering around 100,000 tons annually.

Through Louis Pasteur's (1822–1895) work on microorganisms, the fermentation and soap

➤ INDUSTRIAL CHEMISTRY AND COAL TAR

Coal tar, a waste product from distilling coal, enabled an entire new field of chemistry to emerge. As academics studied separation techniques of this flexible hydrocarbon, industry was pushing scientists to derive more useful products in the 1850s. Consequently, coal tar became a target for a synthetic version of quinine, a rare but effective treatment for malaria. While investigating this problem, Sir William Henry Perkin (1838–1907) failed to synthesize quinine but produced a synthetic dye instead. His purple liquid, called mauveine, dyed fabrics such as silk an attractive color. Perkin's color, now known as mauve, caught on with Queen Victoria and found favor with the court of Napoleon III. Perkin's mauve was the first aniline dye and the first popular synthetic color derived from coal. Today, there are more than 2,000 artificial colors derived from coal tar's aniline and other products such as anthracene, toluene, and benzene. Perkin's work inspired rapid advances in a wide range of fields, including medicine, food, perfumery, explosives, and photography. In photography, coal tar colors improved the sensitivity of photographic emulsion.

—Robert Koslowsky

industries benefited from the demand created by public awareness of the importance of personal hygiene. The resulting demand for soap led to greater demand for alkali. Demand was satisfied in part through the production of synthetic alkali introduced by large companies such as the British firm United Alkali Company, formed in 1890. The Leblanc alkali process, used to produce soda ash for the soap, paper, glass, and textile industries, was wasteful, only achieving a six-to-one ratio of raw materials to useful product. This level of inefficiency and attendant environmental damage that the Leblanc plants caused gave way to the adoption of the Solvay ammonia-soda process, with a 70 percent cost improvement. Coupled with the British Alkali Act of 1863, an attendant environmental solution to hydrochloric acid being released into the atmosphere was found by the chemical industry. Charcoal to absorb the gas in the smokestacks was used to ensure that no more than 5

percent of the hydrochloric acid was vented into the atmosphere. By 1900 the Solvay process accounted for 90 percent of the world's soda production, which was dominated by the British. In the 1870s, 200,000 tons of soda were produced each year, more than all of that produced by the other nations combined.

Chemistry applied to the coal industry led to discoveries of new products. By heating coal without air, coke is made for its value as a reducing agent for metal ores. Two by-products result: coal gas, a flammable gas, and coal tar, a thick black liquid. Initially considered waste, both by-products found useful homes. Coal gas illuminated houses and lit street lamps in the early 1800s and also provided the fuel in Bunsen's burner. Coal tar was employed as a wood preservative and later became the feedstock for a whole host of aromatic organic compounds. Distillation and manipulation of coal tar yielded compounds such as benzene, naphthalene, and the phenols used to develop a wide array of synthetic compounds. The creation of a pharmaceutical industry, development of synthetic fibers, the rise of the explosives industry, and emergence of plastics as the preferred manufacturing material all have their roots in the evolution of organic chemistry.

Such discoveries of synthetic material were significant for another reason. Chemists and academic researchers realized that chemistry could make them rich, and many were thus motivated by the prospect of financial gain. Such considerations led to the development of the field of organic chemistry. Manufacture of synthetic dyes and incorporation of factory production techniques coupled with the use of electricity replaced the traditional craftsman. The textile industry in part drove the need for chemical companies to produce tons of product, and they did.

The nineteenth century saw the foundation of many large chemical companies. In 1802 the DuPont Company was founded by Eleuthère Irénée du Pont, a recent immigrant from revolutionary France. Gunpowder, DuPont's initial product, helped open the American frontier in the nineteenth century. During the latter half of the nineteenth century Germany assumed leadership in the industrialization of organic

chemistry by exploiting the dye-making process. Bayer (1863), BASF (1865), and AGFA (1867) targeted the textile industry with lower-cost synthetic dyestuffs. Prior to World War I, Germany produced almost 300 million pounds (136 million kilograms) of dyes and held an almost 90 percent share of the world market. Bayer developed in-house research facilities to ensure its competitive edge, while advances made by BASF led to the Haber process. Between 1908 and 1912 the synthesis of ammonia pioneered by Fritz Haber (1868–1934) led to new fertilizers and the ability to wage chemical warfare. American innovation in industrial chemistry was exemplified by Dow (1897) with its production of bleach and potassium bromide products, which displaced the traditional European sources. These American rivals to European suppliers triggered a battle for international dominance of the global industrial chemical business early in the twentieth century.

Paper

The ancient craft of papermaking was twice transformed in the nineteenth century, emerging as the modern pulp and paper industry. The first Industrial Revolution, which introduced mechanization, eliminated human speed and stamina as prime constraints on the productive process but created a new bottleneck in papermaking: adequate supplies of raw materials. The second Industrial Revolution introduced new mechanical and, more importantly, chemical methods of utilizing wood, allowing paper to be produced in prodigious quantities in a growing number of applications.

Although the pulping process had been partially mechanized in the late seventeenth century with the introduction of hollanders (pulping engines), papermaking remained a manual process. Papermakers placed a wooden mold (frame) with a mesh or screen attached to it in a vessel filled with pulped fibers suspended in water. They moved the mold from side to side so that the fibres would be deposited evenly on the screen. The mold would then be taken out, and the wet sheet of paper was removed and dried. The traditional papermaking material was “rags,” scraps left over from textile manufacture. The introduction of the papermaking or Fourdrinier machine in the first decade of the nineteenth century revolutionized this process. The concept for such a machine, first invented in France by Louis-Nicolas Robert in 1799, was brought to England, where it was perfected by mechanic Bryan Donkin with funding from the Fourdrinier firm of stationers.

The great increase in the speed of papermaking plus growing demand for paper and paper products created a crisis in the supply of rags by the middle of the nineteenth century. A variety of materials including straw and esparto grass were pressed into use, but these only represented stop-gap measures. The basis of a solution appeared in 1843 when F. G. Keller invented the technique of mechanically grinding wood pulp with a revolving stone. Commercial use followed in the next decade, beginning first in Germany. This was followed by a trio of methods for chemically pulping wood, dissolving away the noncellulose components of the wood. Soda (alkali) pulp first appeared in the 1850s, then sulphite pulping appeared around 1870, and sulphate pulping appeared a decade later.

With the supply of paper now constrained only by the ecological limits of the world's softwood (spruce, balsam, hemlock, and later pine) forests, the pulp and paper industry grew phenomenally in the early twentieth century. While fine grades of writing and book paper remained important and new packaging and sanitary products entered the market, newsprint was the engine of this growth. The ability to supply the seemingly endless demand for cheap newsprint benefited the economies of the Scandinavian countries, the United States, and especially

Canada. After the 1913 repeal of the U.S. tariff on newsprint, Canada came to supply almost two-thirds of world export markets for the product.

Printing and Publishing

The history of printing and publishing between 1750 and 1914 is intertwined with complex networks of production, dissemination, and consumption of printed materials, including such factors as economics, technology, education,

and cultural and social contexts. The equipment and procedures for letterpress printing did not change much from the fifteenth through the eighteenth centuries. Books were expensive relative to income. Most people, especially the poor, lacked adequate education for effective reading. In 1750 the commissioning, production, and distribution of books were still largely concentrated in the hands of printers. Most books were sold in sheets (i.e., as folded, unstitched bundles of paper), which the purchaser would pay a bookbinder to bind. Publishing firms, subcontracting such tasks as printing and illustration to production specialists and selling finished case-bound books through retailers, came into being and flourished in the nineteenth century.

The century also witnessed revolutions in industrialized production. Iron presses replaced wooden presses. The German Friedrich Koenig developed steam-powered cylinder presses (1811) that rolled sheets on revolving cylinders onto flat beds of type. At 1,100 sheets per hour, Koenig's invention (first used commercially in 1814 by the *London Times*) tripled the speed of previous presses. In the United States Richard Hoe (1846) invented the rotary press (revolving cylinders held type as well as the paper to be printed and could produce 20,000 sheets per hour), and William Bullock (1865) developed a high-speed web rotary press that used continuous rolls of paper.

John Baskerville (England, 1754) designed improved and more legible types, which greatly influenced the appearance of the printed page. By 1830 stereotypes (metal casts of pages of type made from papier-mâché molds) freed loose type for reuse and allowed whole books to be set in type before printing began. The plates could be stored in anticipation of future printings of the same work. Electrotyping (after 1837) similarly produced facsimiles of pages of set type. A wax mold was coated with graphite and submerged with copper in an acid bath. Copper ions, attracted by an electrical charge to the surface of the matrix, built an electroplate facsimile that could be reinforced and used for printing. Movable type was set by hand by compositors until 1884, when Ottmar Mergenthaler, a German immigrant to the United States, devised the linotype machine, allowing

▶ WILLIAM MORRIS AND THE PRIVATE PRESS MOVEMENT

William Morris (1834–1896) was an English author, artist, and printer who deplored the ways in which craftsmanship was being supplanted by machinery in the mid- to late nineteenth century. He was a principal influence on the arts and crafts movement and founded the Kelmscott Press. Such private presses produced hand-printed books (ca. 1890–1940) in small runs as a response to the overall decrease in book-production standards, which started around 1800 but accelerated in the mid-nineteenth century because of mass production. Painstakingly produced books such as the Kelmscott edition of *The Works of Geoffrey Chaucer*, printed by hand on handmade paper and lavishly illustrated by pre-Raphaelite artist Edward Burne-Jones, are monuments to the private press movement's rebellion against slipshod production. Private press proprietors typically created beautiful objects instead of books that were convenient to read, but the movement had positive influence, reminding commercial publishers that more attention should be paid to design and quality.

—Jeffrey Mifflin

keyboard operators to cast whole lines of type in one slug. Other key developments included the American Tolbert Lanston's Monotype machine (1887).

Improved technology for printing illustrations included the development of wood engraving (Thomas Bewick, England, perfected the technique, ca. 1790), lithography (Alois Senefelder, Austria, 1798), photolithography (Alphonse Louis Poitevin, France, 1855), and the halftone screen (Louis and Max Levy, United States, in the 1880s). Around 1905 the American Ira Rubel perfected offset printing on paper, whereby inked images were transferred first to a rubber-covered cylinder and then printed from cylinder to paper, a technique widely adopted in the early twentieth century.

By the late 1800s the printing, publishing, and reading communications network was predicated on interlocking components such as printers, publishing houses, producers of newspapers and magazines, booksellers, lending libraries, writers, readers, and transportation. The Industrial Revolution's machines required at least some workers with sufficient reading ability to understand printed instructions. Wider public education engendered more and better readers. Trade unions won increased leisure for workers, and demand followed for a variety of affordable reading materials. Newspapers, general interest magazines, scholarly journals, religious tracts, serial novels, and other publications proliferated. Steam-powered printing, machine-made wood pulp paper (replacing expensive but more durable rag-based paper, ca. 1850), faster typesetting, education, improved distribution, and public libraries led to increased access to information for a larger proportion of the population and expansion of public awareness, including wider political and cultural sensibilities. Best-selling authors such as Mark Twain and Charles Dickens spearheaded campaigns for legislation that eventually led to more effective protection of copyrights against pirated editions in the late nineteenth century.

By 1914 the availability of radio equipment for receiving wireless signals foreshadowed the radio broadcasts that would soon compete with print for the public's attention.

Internal Combustion Engine, 1798–1897

The invention of the internal combustion engine is commonly confused with the building of the first automobile, but the invention of the first actually predates the latter by almost a century. An internal combustion engine is defined as one in which the fuel is burned internally (usually in a cylinder) and the force of the heated gases is used to power the machine.

One of the earliest of these machines is reported to have been developed in 1798 by the American inventor John Stevens (1749–1838). While little is known about Stevens's machine, it is believed to have functioned by igniting alcohol in a chamber, which in turn drove a piston upward. Over the next several years Stevens made a number of improvements in the design. However, it is unclear whether this machine was used for any purpose other than demonstrations. Alcohol was not the only fuel attempted in the early part of the nineteenth century. Coal gas and gunpowder were also experimented with as a method of driving the pistons. One of the more interesting ideas was invented in 1820 by the Englishman William Cecil (1792–1882). Cecil used hydrogen gas as the fuel for his internal combustion engine.

► THE ROTARY ENGINE

The four-cycle gas-powered engine was not the only design for an internal combustion engine that was attempted in the nineteenth century. One alternative form of engine was the rotary engine, which attempted to reduce the waste of force associated with the up-down movement of the four-stroke engine by attaching the cylinders in such a manner that they rotated around a central axis. Because of engineering challenges this design was never very successful in the nineteenth century, although a number of manufacturers have attempted to design similar engines since then. One notable designer is Felix Wankel, who spent decades developing a rotary engine that several automobile manufacturers experimented with beginning in the 1960s.

—Michael Windelspecht

Multiple designs for internal combustion were explored in the mid-nineteenth century. In 1860 a Belgian inventor named Etienne Lenoir (1822–1900) developed a prototype of the internal combustion engine that most closely resembles the modern version. Lenoir's engine was powered by gasoline, a fuel that was gaining popularity in the mid-nineteenth century; however, the earlier forms of these machines did not use gasoline. Lenoir's machine used a form of a spark plug that was connected to a battery. By the 1860s battery technology had progressed to the point that batteries were reliable and powerful enough to be used as an external energy source, although due to the lack of a generator Lenoir had problems keeping the batteries charged. He also pioneered the effective use of a distributor that delivered the electric power from the battery to the cylinders to allow for a sequential means of igniting the fuel. Lenoir's first machines had an estimated output of four horsepower.

Lenoir produced a number of variations of the internal combustion engine, but he is most often recognized for inspiring the work of the German inventor Nicholas Otto (1832–1891), who along with his team of engineers developed the four-cycle engine (ca. 1876). This does not refer to the number of cylinders but rather to the sequence of events in a cycle of a single cylinder. In the first part of the sequence the piston in the cylinder compresses the fuel-air mixture at the top of the cylinder. Next, a spark is delivered to ignite the fuel, and the expansion of the gases drives the piston downward, generating the force to do the work. In the third step the piston once again moves upward to expel the waste products of combustion (exhaust). Finally, the piston moves downward again, this time creating a vacuum that draws additional fuel into the cylinder. The problem with this process is that the cylinder is only working a fraction of the time, but if multiple cylinders are connected together and the ignition is alternated among them, as is the case on most modern engines, then the machine can provide a constant supply of power. From this point onward engineers in Europe and the Americas worked on improving the basic design of the multicylinder four-stroke engine.

In 1897 the German inventor Rudolf Karl Diesel (1858–1913) designed a form of internal combustion engine that did not utilize a spark to ignite the fuel but instead utilized the direct compression of the gas. Diesel recognized that as the volume of a gas decreased and the pressure increased, the temperature of the gas increased. He reasoned that it should be possible to use that heat as an ignition source. These machines tended to be very large, but they delivered a significantly higher-power output than the spark-ignited engines. In the nineteenth century these engines usually used kerosene, but in the twentieth century a special grade of petroleum called diesel fuel was designed to maximize their output. By the turn of the century the diesel engine was being used in a number of factories in the United States, and the first prototypes and production models for motorcycles and automobiles were being developed by inventors such as Karl Benz and Gottlieb Daimler in Germany and Frank and Charles Duryea in the United States.

Electricity and Its Uses

The process by which electricity was transformed from a scientific curiosity to a powerful technology can be traced back to the 1820s and 1830s. During this period a series of discoveries and observations concerning electrical current and magnetism by the Danish physicist Hans Christian Oersted (1777–1851), the French physicist André Marie Ampère (1775–1836), and the French physicist François Arago (1786–1853) prepared the way for the groundbreaking discoveries of the Englishman Michael Faraday (1791–1867).

In 1821 Faraday discovered electromagnetic rotation, the tendency of a current and a magnet pole to rotate about each other, and in 1831 he discovered electromagnetic induction by

showing that a rotating magnet could induce an electric current in a copper wire. Faraday's discoveries made it possible to generate electricity mechanically, and his work along with that of his contemporaries led to the development of the electric generator, the electric motor, and the transformer. For the next half century, however, methods of producing electricity were so expensive that its uses were limited to tasks for which it was uniquely suited, such as the telegraph and electroplating. Major breakthroughs in electricity use occurred in the 1870s and 1880s, caused in part by the development of new and cheaper methods of electrical generation and in part by soaring demand.

The humble lightbulb plays a key role in this story, for it provided the first mass market for electricity. Spurred by developments in electric generation and the example of the carbon

Edison's system for generating electricity, including the generator, armature and electric meter. Illustrated in *Harper's Weekly*, January 3, 1880. (Library of Congress)

THE VACUUM TUBE

While Marconi recognized the commercial use for wireless, he did not imagine the possibility of mass entertainment. He was thus not too concerned that the spark transmitters he used could only send Morse Code. Others turned their attention to the possibility of continuous transmission. Two promising avenues of research—the alternator, which generated electromagnetic waves while transforming direct to alternating current, and the arc transmitter, which generated waves by passing a current through gas—proved inappropriate despite considerable efforts by industrial research laboratories. The early vacuum tubes looked like lightbulbs, as they were grounded in scientific curiosity about the pattern of discoloration observed in lightbulbs. Edison and others had tried to eliminate this discoloration by inserting a second electrode. John Fleming, an English scientist who had collaborated

with Marconi and also with lightbulb interests, recognized that electrons moved only in one direction between electrodes. The American inventor Lee De Forest (1873–1961) in 1906 inserted a third electrode, apparently as part of trial-and-error experimentation. This third electrode controlled the flow of electrons between the other two, thus allowing the vacuum tube to serve as an electronic valve. Interestingly, De Forest thought that it was ionized gases rather than electrons moving between electrodes and thus did not fully appreciate the importance of the vacuum. Decades of further research at the laboratories of Bell and General Electric were needed before the vacuum tube could be used reliably in radio transmission and reception, telephone transmission, and a variety of other uses.

—Rick Szostak

arc lamp used in lighthouses, several inventors experimented with smaller electric lights suited to home and office. The American Thomas Alva Edison (1847–1931) produced the first commercially feasible lightbulb in 1879. Convinced that the lightbulb could succeed only with a unified system of electricity generation, transmission, metering, and use, he developed such a system in New York City, with coal-fired generators providing electric lighting to thousands of consumers. Similar systems soon were developed in most American and Western European cities. Although Edison favored direct current, it was soon recognized that alternating current suffered less power loss when transmitted long distances. Power loss was no problem for Edison's urban systems but became an important issue with the advent of hydroelectric generation in 1895 at Niagara Falls for distant markets. The American Nikola Tesla (1856–1943) developed an effective alternating current transmission system, and when the Westinghouse Corporation purchased his patent in 1885 this ensured the eventual victory of alternating current.

Once electricity was readily available, innovators developed other uses for it. The first electric streetcar was introduced in Richmond, Virginia, in 1888, and within two years

one-sixth of all American streetcars were electrified. Adoption of electric streetcars was delayed by about a decade in Europe, due largely to concerns over aesthetics and overhead electrical wires, but by 1901 all major European cities had electric streetcars that were quicker, cleaner, and cheaper than the horse-drawn carriages they replaced. Home appliances such as toasters and irons were introduced. Industrial machinery was developed, and industrialists recognized over the next decades that electricity not only freed them from the noise and dirt associated with internal combustion engines connected to machines by belts, but also allowed them much greater freedom in the location and speed of individual machines. These additional uses for electricity were important in that they spread demand more evenly through the day. Lightbulbs were used for a few hours during the evening, and thus generation facilities at first largely lay idle until then. Urban railways, industrial machinery, and home appliances created demand during the day. Electric generation companies soon recognized the advantages of serving diverse uses and actively encouraged daytime and nighttime use of electricity.

As electricity use expanded, a host of advances were made in cables, meters, switches,

fuses, and generators. The efficiency of the lightbulb itself increased significantly. As noted above, electricity had in its earliest days been applied to uses such as the telegraph or electroplating where no other power source could compete. Soon, however, new devices were invented that relied on electricity alone. These included the telephone, whose spread was facilitated by developments in electricity generation, and the first phonograph, which was developed by Edison in 1877. The telephone and phonograph set the stage for advances in radio, television, and a host of other electronic devices. But electronics also depended on continued advances in scientific understanding. Indeed, radio technology flowed directly from scientific efforts to understand the behavior of electromagnetic waves. The English scientist Oliver Lodge (1851–1940) exhibited the first wireless transmitter as a scientific curiosity in 1894. By 1901 the Italian Guglielmo Marconi (1874–1937) had not only produced a practical device for ship-to-shore communication but also transmitted messages from Wales to Newfoundland. The vacuum tube was developed at first to make continuous wireless transmission possible. It was the basic electronic device until the invention of the transistor.

Hydroelectric Power

The Greek word *hydro* means “water,” and hydroelectricity is electricity made from moving water. To produce electricity, a dam is first built across a river to hold rainwater or melting snow in a reservoir. Pipelines called penstocks, which regulate water drop from the high point of the reservoir to a low point downstream of the dam, provide a steady volume of flowing water. This difference in elevation and the flow volume

define the generating capacity of the power plant. Falling water passes through turbines, and the resulting mechanical motion is converted to electricity by generators. The realization that moving water could produce not only mechanical power but also electrical power, coupled with the ease of transmitting it over great distances with little loss of energy, helped spur the second Industrial Revolution.

The first hydroelectric power plants appeared in the late nineteenth century. One such facility was the Wolverine Chair Factory of Grand Rapids, Michigan, where in 1880 16 electric lights were powered. Another such plant, built across the Fox River in Appleton, Wisconsin, began operating in 1882 and generated 12 kilowatts of power, enough to power 250 electric lights. The long-distance transmission of hydroelectric power was first demonstrated at the Munich Electrical Exposition in 1882. Direct current of 2,400 volts was generated at Miesbach, Germany, and the power was transmitted to Munich, 37 miles (60 kilometers) away. The first European hydroelectric plant was developed in 1883 along the Bush River at Portrush in Ireland. The power was generated by a Siemens dynamo, which in turn provided motive force for the electric tramcars of the Giants Causeway Tramway. Advances in Europe, Canada, and the United States led to the globalization of electricity. By 1889, 200 hydroelectric plants were in operation in the United States, primarily providing light to extend working hours.

Hydroelectric power plants became larger after utility companies began to promote centralized power generation based on the principle that bigger was better. This design philosophy became the model for the building of all electrical power systems throughout the world. The introduction of high-voltage transmission and the invention of the electric transformer provided the impetus for hydroelectric designers to adopt alternating current instead of direct current technology. Credibility for this approach came by way of the Niagara Falls hydroelectric project, built by George Westinghouse (1846–1914) in 1896 for the Niagara Mohawk Power Company. Westinghouse showed the superiority of transmitting power using electricity as the medium rather than mechanical translation

THE WINNIPEG RIVER

In Canada, Quebec and Manitoba are pioneers in hydroelectric power development and generation. In Manitoba, the Winnipeg River was the first waterway harnessed for its energy content. In 1906, electric power flowed from the historic Pinawa Station. Pinawa Station took three years to build and cranked out power for more than 45 years until it was abandoned in 1951 to make way for a more efficient site. Visitors to the site were struck by its similarity to an ancient Roman ruin. The Winnipeg River descends 272 feet (83 meters) in a series of falls and rapids and offered great potential for future electric production. This proved prophetic, as the second hydroelectric plant, Pointe du Bois, was built by the city of Winnipeg in 1911. Five more such power plants were built to exploit the full hydroelectric potential of the river. As energy demands grew across the province, energy planners expanded their sites northward to the mighty Nelson River. World-leading direct-current high-voltage transmission technology was developed as a result.

—Robert Koslowsky

Aerial view of Pinawa Generating Station on the Winnipeg River. (Manitoba Hydro)

using ropes with waterwheels; the company also demonstrated the transmission advantages of alternating current as advocated by Nikola Tesla (1856–1943) over direct current, advocated by Thomas Edison (1847–1931). The significance of placing generating stations at the falls, 20 miles (32 kilometers) from the main consumption center, Buffalo, validated the practice of long-distance electrical transmission. Westinghouse convincingly used the Niagara project as a model for centralized power generation, standardizing the generator size for the era and providing electricity for a diversity of uses including electric rail, lighting, and machine power.

Westinghouse conversely proved that small local hydro developments could not meet the increasing demand for power. Whereas public utilities had been early advocates of both large and small hydro developments, Westinghouse's large-scale technological approach and Sam Insull's (1859–1938) fervor led to massive generating units and the selection of hydroelectric sites with the potential to achieve significant economies of

scale. Meanwhile, Tesla's insistence on using an alternating current of 60 cycles per second was based on practical considerations of operating efficiency and remains the standard to this day.

The view that energy independence was essential for economic growth and security for a nation led to government intervention in the electric power industry. In the case of the United States, the military was chosen to ensure the widespread adoption of electrical power. Among the early tasks of the U.S. Army Corps of Engineers, major river systems, like the Ohio and Mississippi, were to be kept open for navigation. This meant clearing waterways of snags and sandbars. From this early mission, the Army Corps of Engineers' role expanded to include management of hydroelectric power generation. In 1909 a dam on the St. Mary's River in Michigan became the first hydroelectric facility acquired by the federal government. The U.S. Congress recognized that electric power was important for industrial growth and subsequently passed legislation authorizing the Corps of Engineers to evaluate the

suitability of the nation's hydroelectric sites. By 1916 the first hydroelectric project was completed by the Corps of Engineers, and from there many more large-scale installations were established, one of which was the Tennessee Valley Authority (TVA) in the 1930s. By this time hydroelectric power accounted for 40 percent of the country's total electric power generation, and the budding national electric grid propelled both the Second Industrial Revolution and America's rise to global industrial leadership.

Rubber

Rubber is an elastic, waterproof material derived from the sap (latex) of tropical trees. In the late nineteenth century, the Amazon Basin experienced an economic boom owing to rubber's emergence as a world commodity, and the subsequent bust after 1910 has placed rubber prominently in the larger debate concerning Latin America's failure to develop.

For centuries, the indigenous inhabitants of Latin America employed rubber in a variety of products: it formed the balls of Mesoamerica's ancient games, and Amazonian tribes used it to waterproof textiles and mold containers. But it was not a product of immediate value to Europeans. Charles-Marie de La Condamine introduced rubber to Europe only in the 1740s, but while its unique properties impressed Europeans, even by the 1830s it was employed only in limited applications such as mackintosh raincoats and erasers (the latter the source of the English term "rubber"). Natural rubber's inconsistent texture over a small range of temperatures limited its utility. When cold, raw rubber was brittle and prone to crack; when warm, it formed a malodorous sludge. Only with Charles Goodyear's

1839 discovery of vulcanization, which stabilized rubber chemically by the introduction of sulfur, did rubber find a sustainable market.

Pneumatic tires for bicycles and automobiles and the need for electrical insulation created the spike in world demand for rubber at century's end. Of the variety of natural sources, *Hevea brasiliensis*, found along the southern tributaries of the Amazon River, was of the highest quality. The region, from Brazil to Peru and Bolivia, was linked to the wider world for the first time by steam navigation and rail. Rubber barons in the cities of Belém, Manaus, and Iquitos controlled rubber production through a network of debt with traders and tappers and, with their growing wealth, built stately homes and imported European delicacies. Remote Manaus, at the Amazon Basin's geographic center (or 620 miles [1,000 kilometers] from the mouth of the Amazon), enjoyed electric lighting and trolleys before most European cities.

In the forests, however, rubber collection remained primitive. Isolated tappers wandered

Weighing rubber on a Brazilian rubber plantation, early twentieth century. (Library of Congress)

► GOODYEAR'S BREAKTHROUGH

Charles Goodyear's discovery of vulcanization created a revived rubber industry almost overnight. Although there was great interest in rubber products in the 1830s, the inherent qualities of rubber limited its use. Goodyear found that rubber, when heated with sulfur, became more durable and thus more useful. When Goodyear's process was patented in 1844, he received commendations from prestigious people in government, including Andrew Jackson. However, the ease with which his process could be duplicated caused others to infringe upon his patents. Although Goodyear's lawyer, Daniel Webster, won a victory in a patent infringement case in 1852, Goodyear continued to suffer business reverses and died in debt. Frank Sieberling named his company the Goodyear Tire and Rubber Company in 1898 in homage of Goodyear.

the upland forests, tapping scattered trees in the morning to return and collect the latex in the afternoon. In this extensive mode, the region's supply could not match world demand, and the price of rubber rose at rates that inevitably invited competition. As early as 1876, British adventurer Henry Wickham smuggled 70,000 rubber seeds to London's Kew Gardens. Once germinated, the seedlings were replanted in tidy, efficient plantations in Asia. By 1913, Asian plantations, which had produced almost no rubber in 1905, matched the Amazon's entire production; by 1919, the volume of Asian rubber exports exceeded the Amazon's by more than seven times. The price of rubber fell below the Amazon's costs of production, and the consequences for the region's economy were catastrophic.

To understand the bust, scholars have attempted to explain why the Amazon region did not develop a plantation system. Many researchers have focused on the structural relations of tappers, traders, barons, and foreigners, some of whom emphasized the role of dependency in limiting local capital accumulation. Others point to a lack of interest by the local elite who enjoyed massive profits by restricting supply, and yet others highlight the resistance of tappers and local traders who preferred their independent lifestyle over the perceived strictures of a plantation regime. Still others have investigated environmental limitations; an endemic disease, South American leaf blight, defeated every significant attempt to establish plantations, including heavily capitalized ventures by capable entrepreneurs such as Henry Ford. Rubber tapping remains a minor extractive activity in the Amazon and has been a recent victim of the expansion of ranching.

■ Introduction: Technologies to Communicate and Record

The entries in this section provide information about the electric telegraph, telephone, and wireless, three inventions that transformed communications; they also discuss the phonograph and still and motion picture cameras, which enabled human beings to record the

sights and sounds of life with unerring accuracy. All of these breakthroughs were made by European or American inventors, some working more or less independently and some as part of laboratory research teams. Unlike technological breakthroughs of earlier eras, which were made by

inventors with little scientific knowledge or training, these inventions all were made possible by basic scientific research in the nineteenth century. The research of Michael Faraday (1791–1857) on electromagnetic induction made possible the telegraph, the telephone, and indirectly the phonograph and the cameras and projectors for making film. The work of James Clark Maxwell (1831–1879) and Heinrich Hertz (1857–1894) on electromagnetic waves paved the way for Marconi's development of the wireless. Advances in chemistry contributed to the development of photography and the making of moving pictures.

Of the new technologies covered in this section, the electric telegraph, although soon to be pushed aside by the telephone and radio, was the most important in the nineteenth century. The electric telegraph made possible the safe scheduling and dispatching of trains, gave generals a powerful instrument to control troop movements before and during battles, and enabled European officials and businessmen to monitor events and issue orders across the globe. Still photography, like the electric telegraph, also was developed early in the century, and by the early 1900s was an established part of journalism, an art form, and, after the invention of the inexpensive Kodak camera in 1888, a source of enjoyment for millions. The phonograph, the radio, moving pictures, and the telephone were developed relatively late in the nineteenth century and reached their potential in terms of popularity and usefulness in the twentieth century, when they too became part of the fabric of modern life.

—*James H. Overfield*

Invention of the Telegraph

Telegraphic systems have been common throughout human history and have been employed in various forms, including smoke signals, semaphore, pigeon carriers, and the signal towers used by Claude Chappé during the French Revolution (1789–1799). The earliest electric telegraph systems emerged over several decades in the context of broader advances in science and technology associated with the Industrial Revolution.

The practical implementation of the electric telegraph was dependent upon three discoveries

in electrical engineering. In 1800 Alessandro Volta (1745–1827) invented the voltaic pile, which used stacks of silver and zinc discs to generate small amounts of electricity. These rudimentary batteries were soon developed further, allowing the electrical charges being transmitted through telegraph lines to be sent over longer distances, thereby solving the problem of signal loss through poor insulation. In 1819 Hans Oersted (1777–1851) pioneered the theory of electromagnetism by showing that electric current held in a coiled wire caused a magnetized needle to orient itself in relation to the wire, allowing the development of electromagnetic telegraph receivers that could record telegraphic messages. Finally, in 1827 George Simon Ohm (1787–1854) published his law of electrical circuits, proving that the voltage of any circuit was both proportional to the charge going through it and varied in relation to the resistance levels of the circuit, allowing electrical engineers to begin to calculate the specific requirements of proposed electric telegraph networks.

The first public system was demonstrated in 1837 by William F. Cooke and Charles Wheatstone in England on the Euston to Camden railway. By 1839 Paddington and West Drayton were connected, and by 1843 the line had been extended to Slough. These early telegraph systems tended to be used for government purposes, but in 1846 Cooke and Wheatstone formed the Electric Telegraph Company and began installing more than 6,000 miles (9,656 kilometers) of line across Britain, allowing the extension of the service to the wider public. By the late 1840s Britain's telegraph network consisted of overhead lines composed of single strands of copper wire strung on poles and underground lines insulated with tarred cotton. Electrical impulses moved needles, which pointed to letters of the alphabet printed on cards.

In the United States Samuel Morse had been experimenting with telegraphy since 1832, unaware of the work by Cooke and Wheatstone. Morse developed and patented a quite different system, using electromagnetic signals to make impressions on paper in a code composed of dots and dashes. The use of code enabled messages to be greatly compressed and therefore transmitted at greater speed; the receiving method increased

THE TAWELL MURDER

The electric telegraph was used to apprehend a murderer only a few years after it was first established by Cooke and Wheatstone. A man named John Tawell had poisoned his lover on New Year's Day 1845 and was later noticed boarding a train at Slough. A telegraph was sent to Paddington station, where police identified and arrested Tawell.

The story captivated Victorian England and was widely reported in newspapers and popular magazines. Tawell was tried and convicted and was hanged in front of a crowd of 10,000 people. For some time afterward, Londoners referred to the telegraph as “the cords that hung John Tawell.”

efficiency further still. Morse also invented a relay system that re-created the original signal for further transmission after 20 miles (32 kilometers), thus extending the range of the system. In September 1837 Morse demonstrated the first American line. Congressional and public apathy meant that the first public line (Washington to Baltimore) did not come into regular service until 1844. In the United States Morse Code became the standard cipher used in telegraphy in 1845, and by 1852 there were more than 18,000 miles (nearly 29,000 kilometers) of line over the eastern third of the United States. The Western Union Telegraph Company was established in 1851, and telegraphic coverage extended rapidly, only held in check by the problem of traversing oceans.

After many difficulties developing adequate technology, long-distance submarine telegraphy was established with the successful laying of the Atlantic Cable in 1866. Over the next decades the world telegraph system extended rapidly through a combination of private enterprise and government subsidies and was not supplanted until several decades after Guglielmo Marconi transmitted the first wireless signal across the

Atlantic on December 12, 1901, establishing wireless telegraphy as an emergent technology.

World Telegraphy, 1850–1914

The world telegraph system of the late nineteenth and early twentieth centuries formed part of a broader communications network composed of shipping, railways, canals, and port cities. Telegraphic communication connected distant societies and was crucial to early-twentieth-century developments in economics, culture, and diplomacy. On January 21, 1871, a contributor to *Notes and Queries* referred to the network as “the nerves of the earth,” and many commentators were startled by the way in which the telegraph altered conceptions of time and space.

Although basic electric telegraph systems were in existence from the beginning of the nineteenth century, they were not fully established until the 1850s. The technology was quickly diffused worldwide, however, and by 1862 the world's telegraph system was almost 150,000 miles (241,500 kilometers) in length. Truly international telegraphic communication depended on the development of reliable submarine cables that could withstand conditions on the sea floor and provide adequate insulation for long-distance transmissions, as batteries could not be used to extend the signals. The German Werner von Siemens laid the first successful underwater cable across the Rhine River in 1847 and in Kiel Harbor later. Rapid developments were made during the 1850s as governments competed to improve their communications systems. Early cables used tarred cotton as insulation, but this insulation proved unreliable and was replaced with gutta-percha (a form of rubber) and high-conductivity wire. London was

linked to Dover in 1846 and France in 1851. A number of failures led to stricter engineering standards, and in 1857–1858 the American Cyrus W. Field, under the Anglo-American Telegraph Company (1852), successfully laid a transatlantic cable before an operator inadvertently disabled it by sending 2,000 volts down it. The cable was not repaired until 1866, after the American Civil War, but eventually gave excellent service and effectively connected the United States with Britain and continental Europe. Financial markets responded positively to the virtually instantaneous flow of information available, and telegraphic entrepreneurs and governments immediately saw the possibility of commercial gain in extending the network further still. The International Telegraph Union was established in Paris in 1865.

Extension of the world telegraph network was extremely competitive, expensive, and financially volatile. High costs per message meant that the majority of telegrams sent and received were from commercial and government sources, and the technologies used were not entirely reliable until the early twentieth century. Many lines suffered outages of several months, and small companies found it difficult to compete. This led to the development of several major companies devoted to extending the world telegraph system, including Siemens and Halske Telegraph Construction Company of Germany (1847), Western Union Telegraph Company of the United States (1851), and the dominant Eastern Telegraph of Britain (1872). Myriad smaller companies and subsidiaries of the major companies developed over the years as new telegraph lines were requested from governments and private individuals. Large cable manufacturing companies also evolved, such as the Telegraph Construction and Maintenance Company (Telcon, later Cable and Wireless), controlled by John Pender, the British telegraph magnate who was also chairman of Eastern Telegraph and its various associates, thus cornering the operational, construction, and maintenance markets.

The bulk of the world's telegraph lines were constructed by British interests. As the dominant industrial and commercial center of the late-nineteenth-century and early-twentieth-century

The American steamship Niagara lays the telegraphic cable that would run from the Atlantic coast of Ireland to St. John's, Newfoundland, from The Illustrated London News, August, 1857. (Corbis)

world, Britain had the infrastructure and financial power to achieve major technological projects such as the development of a world telegraph network. As ruler of a vast empire, stretching from Africa to Oceania, Britain also had the necessary motivation to extend the telegraph system. In the context of ongoing tensions with continental powers and extensive commitments in the colonies, British strategists suggested that the empire required an “All Red Route” of telegraph lines that circumnavigated the world and only touched on British-controlled territory. This would unite the far-flung empire and allow fast deployment of military personnel and equipment when necessary, with the utmost security of information.

This goal was achieved remarkably quickly. By 1876 the British Empire was connected by cable as far as New Zealand in the South Pacific, and by 1902 the 6,900-mile (11,104-kilometer) Pacific Cable completed a full circumnavigation of the globe. By the twentieth century 60 percent of the world's cables were British. Multiple Eastern Telegraph lines reached from Britain to Russia, the Middle East, India, Asia, Africa, the United States, Canada, Australasia, and South America, allowing communications that previously took weeks or even months to be achieved in only minutes or hours as the messages were relayed across stations. As demand rose the

NEWSPAPERS AND TELEGRAPHY

The world telegraph system was of fundamental importance to the expansion of the press and associated media industries. The advent of a world telegraph network led to the development of major news distribution organizations that serviced readerships across the world, in particular Havas (1835) based in France, Wolff (1849) based in Germany, and Reuters (1851) based in England. The three organizations worked together as a cartel to control the industry and block other entrants to the market. In the United States, a demand for news of the Civil War (1861–1865) led to the expansion of the telegraph network by both commercial and military interests, but this did not initially prompt expansion into the world market. The control of European news distribution organizations over cable news information on the world telegraphy circuit and their close associations with large telegraph companies ensured their continued dominance until American companies such as the Associated Press and United Press International entered the world market after World War I. The exponential increase in up-to-date information prompted an acceleration in the internationalization of culture. Financial markets responded to the new sources of information immediately because it offered entrepreneurs, farmers, and merchants instant access to prices of grain and stocks in distant markets, offering more efficient production and exchange.

—James Smithies

companies added additional cables to the same routes so that in many instances telegraph routes were serviced with multiple lines.

Areas of the world without the industrial and financial backing of Britain found it more difficult to connect to the world system. Attempts to build a Russian telegraph network across Siberia and into the Far East took almost 20 years and eventually reached Japan in 1872. However, efforts to connect North and South America failed repeatedly due to lack of funds and only succeeded in the early 1880s. British dominance waned after World War I, as the United States began to adopt a less insular worldview and extended its control over the cable network and as wireless telegraphy became a reality.

The Phonograph

The phonograph is an instrument that permanently records sound onto some medium. The invention by Thomas Edison (1847–1931) of the phonograph, which dates from the 1870s, was the product of a number of advances from earlier in the nineteenth century. The work of Michael Faraday and others had started to define the properties of electromagnetism, and in the 1830s it became possible to use the properties of electromagnetism to send messages by wire over long distances using the telegraph. Almost immediately after the invention of the telegraph, scientists and inventors began to envision a means of transmitting sound over a distance. In the 1870s this resulted in the invention of the telephone, which sparked Edison's interest in aspects of recording and transmitting sounds. The results were refinements in the telephone that greatly increased transmission strength and the invention of the phonograph.

Edison's phonograph was not the first instrument capable of recording sound. In 1857 the French printer and inventor Édouard-Léon Scott de Martinville had designed a device called a *phonoautograph* that could create visual images of sound but lacked the ability to play back its recordings. Other inventors had designed ways of representing sounds on punch cards as a means of programming organs and other musical instruments. Edison's invention grew out of work in the 1870s to design a method of permanently recording signals sent over telegraph lines. To do this he designed a cylinder covered with wax

paper. The incoming signal from the telegraph was transferred mechanically to a blunt needle, which made small depressions in the surface of the wax paper as the cylinder turned. When the process was reversed and played back through a speaker, the operator could hear the original Morse code. Although the device failed (the wax paper did not allow a great enough distinction between the Morse code's dots and dashes), during the trials Edison noticed that as the cylinder was rotated, a distinct humming sound was emitted from the speaker.

In 1877 Edison, along with a group of assistants at the laboratory in Menlo Park, New Jersey, designed the first phonograph for the playback of sound. With tin foil replacing wax paper, as the cylinder turned a needle made small impressions in the tin foil. On playback the needle would vibrate from these indentions, reproducing the sound. The sound quality was poor, but nonetheless Edison received a patent for the device in February 1878, the same year he founded the Edison Speaking Phonograph Company to publicize and market the new machine. Edison at this point was not interested in using the phonograph for music but instead saw it as a time-saving aid for office work such as dictation or as a way to produce speaking books for the blind. However, by the end of the century the Edison Phonograph Company, while still marketing the device for use in business offices, was also competing with several other companies by selling wax cylinders (which replaced tin cylinders in the early 1880s) with two-minute recordings of marches, ballads, blatantly racist "coon songs," hymns, and other music to the general public. Beginning in the 1880s, Edison and other inventors refined the machines and the cylinders to improve quality. In 1901 a method was devised for producing duplicate copies of cylinders by using a harder wax and a molding process rather than a stylus.

Edison's machines were all based on cylinders, but in 1887 the modern form of the phonograph was introduced by the German American inventor Emile Berliner (1851–1929). Berliner's phonograph used a flat disc, often made of hardened rubber. He founded the Berliner Gramophone Company in the United States in 1895, with affiliates in England, Germany, and Canada

to follow. Disc phonographs began to eclipse cylinder phonographs in popularity by the first decade of the twentieth century, and the Edison Company began selling disc phonographs by 1912. The last "disc record" was manufactured in 1929.

The Telephone and Its Usage before World War I

"Be it known that I, Alexander Graham Bell, of Salem, Massachusetts, have invented certain new and useful improvements in telephony, of which the following is a specification." This is how Bell introduced his famous telephone patent filed to the U.S. Patent Office on February 14, 1876. Improving an earlier invention, he employed a vibratory current of electricity and a new additional apparatus for producing electrical undulations upon the line wire. This was the accidental result of Bell's earlier experiments, assisted by the machinist Thomas Watson, to improve his "harmonic telegraph," a device for distinguishing between musical tones and making possible the transmission of several messages simultaneously on a single wire.

Just a few hours later Elisha Gray, Bell's competitor in the race to invent the telephone, filed his own preliminary application for a patent that gave the inventor an additional 90 days to file

WOMEN OPERATORS

By the late 1800s, the number of telephone users in the United States had increased so dramatically that all companies faced several technological challenges, the most important of which was line switching. The solution was the employment of human operators who could manually connect the caller to the person receiving the call by plugging the right wires into a switchboard. The first operators were usually young boys with experience as telegraph clerks and messengers. However, they soon proved to be unreliable, impatient, and rude. Telephone companies soon realized that young, single, and educated women could be ideal in keeping their business going. They were available in large numbers, were thought to possess the inherent qualities of courtesy and patience, and could be paid less than men. Before World War I the telephone operator became an exclusively female occupation, enforcing gender stereotypes for the use of technology.

—*Maria Rentetzi*

the actual patent. Despite the suspicious similarities of the two patents, within a few days, on March 7, 1876, Bell was issued his patent which became a matter of legal dispute when Western Union, the company that controlled telegraphy in the United States and was Gray's financier, realized the potential economic value of the telephone.

On March 10 the first crucial experiment took place at Bell's workroom, proving that indeed the new device was ready to transmit the human voice. An amateur inventor, not a scientist, Bell immediately sensed his invention's economic potential. In May 1876 he exhibited his device at the Centennial Exposition in Philadelphia and spent most of the next year giving demonstrations around the country. By the end of 1877 the telephone was ready for commercial use. Bell and his backers, Gardiner Hubbard, a Boston-based lawyer and financier and Bell's father-in-law, and Thomas Sanders, a Boston businessman and father of one of Bell's students, established the Bell Telephone Company (later to be American Telephone and Telegraph), which soon proved to be a triumphant monopoly. Even though Western

Union tried to compete by locating telegraph offices almost everywhere, controlling competing telephone patents, and continuing the legal contest with Bell's company, the latter prevailed in court. Western Union was forced to sell its telephone interests to the Bell Company in return for 20 percent of all Bell's net profits.

Within two years of Bell's patent award there were about 10,000 Bell telephones in the United States. Subscribers were encouraged to make their own electrical connections and string their own wires, although the company would carry out these jobs for them for an additional fee. Between 1880 and 1884 the number of telephones tripled, even though the typical telephone system was difficult to use. The telephone consisted of a set of three boxes, one containing a battery, another containing the receiver and speaker, and the third containing a magneto generator, a crank, and a bell. The whole system depended on a switchboard, a box where all the telephone lines in a local area terminated. When the caller turned the crank, a light, a bell, or some other signal alerted the operator, a person who manually answered the call and used wires and plugs in the switchboard to connect the caller with the person he or she was seeking. Other problems included weak transmission, noise on the line, and unsuitable signaling systems. In 1881 the Bell Company standardized telephone technology by gaining control of the Western Electric Company, which became the sole manufacturer of Bell's telephone instruments. Despite all the difficulties, the number of telephones reached 228,000 in 1890.

During Bell's monopoly, telephone service consisted of an individual line for which a customer paid an annual flat fee, allowing unlimited calls within the exchange area. On expiration of the original Bell patents in 1893–1894, the company's financial position became increasingly fragile as many independent companies sprang up and claimed shares in profits, especially in rural areas that Bell had largely ignored. By 1900 there were over 6,000 telephone companies, and by 1907 Bell had lost at least half the market. In order to face the competition, Bell telephone rates dropped dramatically, and new sales strategies included the charge by call and the long-distance service. Bell's company was rescued

under the new management of Theodore Vail. Instead of price competition, Vail bought out smaller independent companies, most of which would not expand their long-distance lines. By 1912 Bell owned 58 percent of U.S. telephones, which were now much easier to use because of technological improvements.

In Europe Bell's invention at first attracted little interest, even though Bell himself traveled to Britain and France to promote the invention. In both of these countries, telephone services became state monopolies in 1889, a decision that slowed the acceptance of the technology. In contrast, telephone usage expanded quickly in Germany, where Bell had failed to register his patent and where the inventor and businessman Ernst Werner von Siemens (1816–1892) became the main producer of telephones. The German government also had a monopoly in providing telephone services but successfully established a well-run network open to public access. In 1880 there still were only 1,900 telephones in all of Europe. The number had increased to about 800,000 ten years later. By 1910, however, Germany alone had more than 1 million telephones, and Great Britain had 649,000 connections.

The Wireless

When American inventor Samuel F. B. Morse sent a message by telegraph between Washington and Baltimore in May 1844, few people

imagined that someday messages would be sent without telegraph wires. Yet by the late 1890s, that was exactly what inventors had achieved. The journey that led to wireless telegraphy began in the 1830s, when British physicist Michael Faraday (1791–1867) performed experiments involving electricity and electromagnetic forces. His insights led to further work by Scottish physicist James Clerk Maxwell (1831–1879). Maxwell showed in the 1850s and 1860s that electric and magnetic fields travel through space in waves that are equivalent to the speed of light. Building on Maxwell's theories, in the late 1880s German professor Heinrich Hertz (1857–1894) discovered radio waves; these "Hertzian waves" of electricity finally enabled inventors to transmit messages through the air electronically. As this new technology proved successful, by 1901 the English-speaking press began using a shorter name for it: wireless. And in France, where several inventors were using the new technology, it became known by its initials: le TSF (*telegraph sans fil*), the French words for "wireless."

Most Americans have been taught that Italian-born Guglielmo Marconi (1874–1937) invented wireless, but several inventors were involved in its development. In 1897 scientific magazines were following the exploits of a competitor, Nicola Tesla (1856–1943). The Hungarian engineer came to the United States in the early 1880s hoping to meet his hero, Thomas Edison. Although Edison did not want to hire him, Tesla decided to remain in the United States, where he soon became fascinated by wireless telegraphy. By 1897 he was able to transmit a signal over a distance of 20 miles (32 kilometers). As he sought to get investors and attention from the press, supporters of U.S. inventor Mahlon Loomis (1826–1886) were insisting to newspapers that Loomis had conducted successful wireless experiments since the late 1860s, long before Tesla began his.

As for Marconi, by the late 1890s he was conducting wireless experiments in England. By 1899, Marconi had transmitted a signal across the English Channel, and then in December 1901, a colleague in the Poldhu wireless station in England transmitted the Morse code letter "S" to him at a receiving station in St. John's, Newfoundland, Canada.

▶ REGINALD FESSENDEN'S AMAZING ACHIEVEMENT

Until Reginald Aubrey Fessenden began doing his experiments, wireless was associated entirely with Morse code. But Fessenden believed that wireless could also send voice, and he was determined to prove it. Born in Canada, he came to the U.S. to work with Thomas Edison but then branched out. While working for the Weather Bureau in 1901, Fessenden did his first voice experiments, and by 1905 he was transmitting messages between his home in Brant Rock, near Marshfield, Massachusetts, and a tower in Scotland. Then in December 1906, he performed a public exhibition of voice and music. Some sources say that it occurred on December 21 while others say it occurred on Christmas Eve, but what is not in dispute is the importance of what Fessenden did. By successfully sending voice and music, he created wireless telephony, setting the stage for radio broadcasting.

—Donna Halper

Marconi's success totally overshadowed the achievements of other inventors. Tesla suddenly found himself ignored by the press, but so did Danish inventor Valdemar Poulsen (1869–1942), who was also doing wireless experiments throughout the late 1890s. Poulsen had invented the telegraphone, a rudimentary way of recording sound, and by 1902 he invented his own wireless transmitter called the Poulsen Arc. The German inventor Adolphus Slaby (1849–1913) also did wireless experiments during the late 1890s, and his system had received favorable reviews in scientific journals. In France, Edouard Branly (1844–1940) invented a device called a coherer that could detect Hertzian waves; by 1898, the French entrepreneur Eugène Ducretet (1844–1915) was putting Branly's work to good use, sending wireless messages from the Eiffel Tower. And in Russia at this time, Alexander Popov (1859–1905) did important experiments using an antenna to detect radio waves.

But the public was not so worried about who invented the wireless; what mattered was what it could do. The telegraph had already changed society by making communication much faster. This especially helped journalists and businesspeople, who needed to send

and receive information the same day. But there had often been problems with telegraph wires, which came down during bad weather, and the telegraph could not send messages to the ships at sea. At a time when transoceanic travel was very important, there was a need for reliable ship-to-shore broadcasting. Wireless telegraphy enabled the ships to receive weather reports and other important messages. And in an era before reliable long-distance telephone service, wireless telegraphy was the next best thing. It became so popular that major department stores installed public sending stations, allowing anyone to have a message sent across the country. Meanwhile, a Canadian inventor, Reginald Fessenden (1866–1932), demonstrated as early as 1906 that voice and music, not just Morse code, could be sent by wireless. By 1909, Charles "Doc" Herrold and his wife Sybil were doing a program once a week from San Jose, California; they played phonograph records and even took requests. These experiments would lead to what became known as radio.

Photography

Photography is the process of using light or other radiation to form an enduring image on a light-sensitive surface. Photography's roots go back many years. The principle of the camera obscura, a darkened room (or box) where viewers observed inverted images of brightly lit

scenes projected on a flat surface by light rays admitted through a small aperture, was known in the Middle Ages, and such devices were used as visual aids by seventeenth-century painters such as Jan Vermeer. The camera obscura, light-sensitive surfaces to record images, and chemical techniques to develop and prevent deterioration of pictures were all essential to the invention of practical methods of photography.

In 1802 Thomas Wedgwood (1771–1805), the son of the famous English potter Josiah Wedgwood, experimented with paper soaked in silver nitrate. When decorated glass was laid on top of the paper and exposed to sunlight, the design was copied on the paper but could only be preserved in the dark. Joseph Nicéphore Niepce's experiments during 1816–1833 in France with the effects of light on treated surfaces were promising but less than satisfactory. Parisian artist and diorama entrepreneur Louis Jacques Mandé Daguerre collaborated with Niepce (from 1829 until the latter's death in 1833), sharing information about chemicals and techniques that eventually led to commercially viable photography. Daguerreotypes (first publicly announced in 1839) used highly polished silver sheets, iodized for sensitivity to light. Light from the subject passed through the camera's aperture, creating a latent image on a silver sheet that was developed (brought out) by mercury fumes and fixed (made permanent) by immersion in hyposulfite of soda. Hypo (sodium thiosulphate), discovered by the English scientist John Herschel in 1819, could be used to fix residual salts, an essential stage in the stabilization of photographic images, which otherwise would continue to darken when exposed to light. Almost simultaneously, the English scientist William Henry Fox Talbot announced the success of his negative-positive photographic process, which proved more influential than Daguerre's invention.

The subsequent technical evolution of photography before 1914 is the story of increased light sensitivity (speed) of plates or film, improved emulsions, and greater convenience. Wet collodion plates (1851), gelatin-silver bromide plates (or dry plates, 1871), and celluloid roll film (1889) for use in the American George Eastman's inexpensive and easily portable Kodak

Self-portrait of photographer Robert Cornelius, one of the first daguerreotypes, 1839. (Library of Congress)

cameras are all significant landmarks. Images were printed on treated papers (or other supports such as metal or glass lantern slides, catering to consumer demand) using a variety of processes and formats. Stereographs for insertion in 3-D stereoscopic viewers were popular parlor amusements in middle-class homes. *Cartes de visite*, cabinet cards, and tintypes were common portrait formats. Prints on hand-coated albumen paper were predominant between 1855 and 1895 but gradually gave way to machine-produced continuous-roll emulsion papers. By the 1890s photography, no longer limited to professionals, had become relatively simple, inexpensive, and convenient, enabling families to create a visual record of their lives.

Other pre-1914 developments include photojournalism (e.g., photographic documentation of war by Roger Fenton in the Crimea and Matthew Brady's firm in the American Civil War); documentation of late-nineteenth- to early-twentieth-century social conditions by reformers such as Jacob Riis and Lewis Hines; expanding awareness through photography of distant landscapes

► WILLIAM HENRY FOX TALBOT

W. H. Fox Talbot (1800–1877) experimented independently with photography in England while Daguerre and Niepce were researching in France. Talbot soaked sheets of paper in weak solutions of salt and dipped them, when dry, in silver chloride, a light-sensitive chemical. By 1835 he was using such paper in small cameras to record pictures of his estate, but the images were fleeting. Herschel told Talbot about hyposulfite of soda in 1839, enabling him to fix residual salts on the exposed paper, stabilizing the image and resulting in a practical method of producing paper photographic negatives. Waxing the paper to make it transparent facilitated its use in a negative-positive process. Sunlight passed more readily through less darkened areas of the negative, leaving positive contact prints (calotypes) on silver chloride paper placed beneath. Daguerreotypes are visually stunning traces of the past, but nearly all predigital modern photography stems from the process first introduced by Talbot.

—Jeffrey Mifflin

and cultures (e.g., the work of John Thomson in Asia, Félix Bonfils in the Middle East, and Timothy O'Sullivan in the recently surveyed American West); pictorialism and the Photo-Secession group, led by Alfred Stieglitz, that promoted the photograph's potential for artistic expression; and the development of various means for mass-producing photographic images (e.g., photogravure and letterpress halftone) in books, newspapers, and advertisements.

Photographs have had numerous applications in science, medicine, historical documentation, travelogues, journalism, advertising, cinema, art, and portraiture in addition to serving as personal and family mementos. Once thought by Victorians to be an objective record of reality, photography's subjectivity and potential for manipulating meaning have subsequently been better understood. It has been enormously influential in swaying public opinion, creating a demand for products and services, and molding perceptions. Our view of world history may well be divided into two epochs: the photographic era (wherein photographs help shape our

concepts of the past) and the prephotographic era (before 1839).

Cinema

Cinema, also known as film, motion pictures, the movies, and, in earlier years, photoplay, is an art form in which a sequence of still images is projected or otherwise shown for viewing at a speed that creates an illusion of continuous movement. The viewer's brain retains each image for a fraction of a second longer than the eye, transforming discontinuous pictures into fluid motion through persistence of vision. The development of cinema has stemmed from improvements in technical equipment for recording and projecting movies, increased sophistication in the handling of subject matter, and changes in the film industry's manufacturing and marketing practices.

Cinema's emergence in the late nineteenth century was preceded by various optical toys and machines also predicated on persistence of vision. By the 1850s exhibitors had learned how to project the apparent movement of figures on a rotating Phenakistiscope disk through a magic lantern (a candle-powered slide projector) onto a screen. Improvements in the speed at which still photographs could be exposed, the locomotion studies (sequences of still photographs taken at short intervals to analyze how humans and animals move while running, climbing, leaping, etc.) conducted by Étienne-Jules Marey in France and Eadweard Muybridge in the United States, and the invention of celluloid roll film were important factors leading to the development of motion pictures. George Eastman perfected

celluloid film for use with Kodak cameras between 1884 and 1888. W. K. L. Dickson, who headed motion picture research at Thomas Edison's New Jersey laboratory, used Eastman's film with a newly devised apparatus to photographically record movies of real-life activities as early as 1890. Edison secured patents in 1893 for his Kinetograph (camera) and Kinetoscope (peephole viewer). By 1894 he was marketing his invention to Kinetoscope parlors, where patrons paid for individual viewing of unedited films lasting about half a minute, typically showing street scenes from foreign countries or staged entertainment such as juggling.

Louis and Auguste Lumière in France improved on Edison's peepshows by advancing sprocket-wound film one frame at a time through a projector, stopping each image for a fraction of a second before showing the next (intermittent movement). They found that 16 frames per second was the optimum speed for viewing. Their Cinématographe could make movies as well as project them. The first public demonstration of projected movies took place in a Parisian café in 1895. Unprepared audiences were so alarmed by the verisimilitude of the images on the silver screen that many attendees scrambled to dodge a train that seemed to be hurtling toward them. Early films, shot in black and white, were silent, having no recorded sound track to play with the visual track. Plot developments and essential lines of dialogue printed on intertitle cards were projected for the audience to read. Musicians often played live music reflecting the mood of each scene. Films were typically shown as part of a theater's larger program of live entertainment.

In 1908 ten producers and distributors formed the Motion Picture Patents Company (also known as the Movie Trust) to assert control over the industry in the United States. The Movie Trust's tactics included attempts to restrict the supply of film stock, keeping patented equipment out of the hands of rival companies, and guarding the identity of actors (because popular idols could demand higher salaries). The U.S. Supreme Court eliminated the Movie Trust in 1917, but one of its lasting effects was a shift of independent film companies from the eastern United States to California, where Hollywood became a center of film production.

An advertisement for Edison's Vitascope motion picture device, 1896. The Vitascope was the name Edison gave to his patented version of the Kinetoscope. (Library of Congress)

➤ D. W. GRIFFITH

Soon after 1900 filmmakers started producing fictional stories portrayed by hired actors. Georges Méliès in France introduced the artificially arranged scene. Edwin S. Porter in the United States furthered storytelling techniques by breaking scenes into individual shots, each of which contributed to a more meaningful whole and could be selected, combined, and arranged in a significant order to help audiences become emotionally engaged. Porter's *The Great Train Robbery* (1903) was a seminal achievement. However, the greatest advances in the evolution of cinema were made by the American D. W. Griffith (1875–1948), the father of the movies, at the Biograph studios in the years before 1914. Griffith invented film language in collaboration with cameraman Billy Bitzer by employing such devices as backlighting, fades, flashbacks, cross-cutting, long shots, and close-ups to heighten drama, manipulate tempo, and depict psychological development. His genius as a filmmaker, however, has often been overshadowed by the racist implications of his influential masterpiece *The Birth of a Nation* (1915), which glorified the Ku Klux Klan.

—Jeffrey Mifflin

Appealing actors, identified and promoted in the press, became the first movie stars. High-profile stars emerged in the 1910s, including such enduring icons as Mary Pickford and Charlie Chaplin, who before long became the most recognizable man in the world. World War I (1914–1918) disrupted the European film industry, paving the way for a period of unrivaled American dominance. Feature films grew in length as well as sophistication. Movies, no longer short supplements to live vaudeville shows, became main attractions.

Movies played an important role in depicting and interpreting life for early-twentieth-century audiences. The overall effect that cinema has had in molding behavior, providing

role models, and influencing the aspirations of viewers has not been adequately explored.

■ Introduction: Technology and Transportation

During the period from 1750 to the early twentieth century, revolutionary changes were implemented in the ways human beings moved themselves and the goods they grew, mined, and made. Canal building linked coal mines with factories in industrializing England, the Great Lakes with coastal cities in early-nineteenth-century America, and, once the Suez Canal was completed in 1869, Europe and Asia. In Europe and the Americas, advances in road construction made overland travel faster and more comfortable and prepared the way for the automobile age. The application of steam power to land transportation began when the English engineer Richard Trevithick mounted a steam engine on wheels at an ironworks in Wales and successfully pulled ten tons of iron, five wagons, and 70 men 9.75 miles (15.7 kilometers) in 4 hours and 5 minutes, an average speed of approximately 2.4 miles (3.9 kilometers) per hour. This was the beginning of the railroad age in which thousand of miles of railways were constructed on every continent, with locomotives and their cars traveling close to 100 miles (160 kilometers) per hour by the beginning of the twentieth century. Steam engines initially best

served river vessels carrying goods for inland trade. However, by the second decade of the nineteenth century, steam-powered ships were crossing the Atlantic Ocean and by 1900 were reducing the travel time from several weeks to a matter of days. At the end of the period, the first automobiles and the first successfully flown airplanes, both powered by the newly invented internal combustion engine, were spectacular technological breakthroughs but made their impact felt mainly in the years after 1914.

Advances in transportation technology between 1750 and 1914 tightened the webs of global communication and increasingly allowed for the transference of goods and people across the oceans and around the world. They helped create the industrial revolution and the increasingly globalized world economy of the late nineteenth century. Without them the mass migrations of the nineteenth century would never have occurred. Railways and steamships allowed people to move about countries and continents and across oceans searching for work and supplying labor to industrialized areas. At the same time, populations such as those of the Plains Indians in North America were displaced by the

expansion of the railroad and the ensuing movement of migrants into their lands. Steamboats allowed for the opening up of the interiors of Africa, Asia, and the Americas to European travel and conquest, facilitating the “new imperialism” of the late nineteenth century, with railways consolidating those conquests. Finally, with Thomas Cook and Son, in the 1840s, realizing the potential of these developments in transportation technology, tourism emerged as a major multinational business.

—Rodney McCaslin

The Development of the Railroad

The most important technological development of the Industrial Revolution was that of the railroad. Other devices or machines revolutionized individual trades with secondary effects over a wider segment of society, but railroads had an impact over the entire spectrum of the economy and profound effects on society. Locomotives went from George Stephenson’s Rocket that blazed down the track at a blistering 12.5 miles per hour (mph) in 1829 to the Great Western Railway’s City of Truro, which claimed to break the 100-mph mark during a special run in 1904. Railroads went from a single operational commercial line of some 32 miles in 1830 to networks that spanned entire continents by the end of the century. This surge of construction drove the development of heavy industries, providing first the needs of the railroads and later the industrial base for further economic expansion.

George Stephenson (1781–1848), the English engineer who built the first steam-driven public railway, did not invent the idea of rail transportation. The concept of moving heavy loads using railed tramways appears as early as 1556 in Georgius Agricola’s *De re metallica*. Nor did Stephenson invent the locomotive, an honor generally accorded to Welsh inventor Richard Trevithick (1771–1833) and his series of road and rail engines starting in 1801. Nor was Stephenson the only man developing more powerful locomotives during the 1820s. But he is widely hailed as the father of the railroad. His strength was the promotion of the idea and boundless confidence in his abilities. He managed to convince

the directors of the Stockton to Darlington railroad that his steam engine could out-perform the horses they planned to use and proved it. Whereas a horse could move 10 tons at 2.5 mph on rails, his locomotive hauled an estimated 90 tons at an average of about 8 mph on the first trip (September 27, 1825). His later locomotive, Rocket, won the Rainhill Trials held in 1829 by the directors of the new Liverpool to Manchester railway, the first route to offer scheduled passenger service. Ten locomotives were initially entered in the competition, but only five showed up; of those, three actually took part. Stephenson’s locomotive successfully hauled a load three times its own weight at a speed of 12.5 mph. Without a load he astounded the spectators by hitting upwards of 30 mph. This victory won him a £500 prize and a contract to produce engines for the railroad and tied his name inextricably to the development of early railroad technology.

That technology exploded after the success of the Liverpool and Manchester railway. The directors of the route had hoped to make £50,000 per annum on freight charges. In their first year they made £80,000 on freight and £101,829 from passenger fares and paid an 8 percent dividend to their investors. Objections to railways, mostly from competing shipping methods, evaporated, and investors and engineers came together to create the first railway construction boom. By 1840 Britain boasted almost 1,500 miles of track, and in other nations entrepreneurs had started driving spikes of their own. By 1860 the continent had laid more than 20,000 miles of track, the British had increased their rail network to more than 9,000 miles, and in the United States, where vast distances separated population centers, more than 30,000 miles of track were in service. Plans for a transcontinental railroad in the United States were hampered by the American Civil War, but in 1869 the ambitious plan to link the Atlantic and Pacific coasts by rail was accomplished. This rapid growth is even more remarkable in light of the technology available to the builders in the first half of the nineteenth century: these lines were built largely with manual labor, without the benefit of steam shovels or jackhammers.

THE BRAVE LITTLE SHE-DRAGON

Actress Fanny Kemble described her experience as a guest aboard an early locomotive driven by George Stephenson.

“You cannot imagine how strange it seemed to be journeying on thus without any visible cause of progress, other than the magical machine with flying white breath and rhythmical unvarying pace, between these rocky walls that are already clothed with mosses ferns and grasses . . . swifter than a bird flies. You cannot conceive what that sensation of cutting the air was. . . . When I closed my eyes this sensation of flying was delightful, and strange beyond description; yet strange as it was, I had a perfect sense of security, and not the slightest fear. At one time, to exhibit the power of the engine, having met another steam engine, which was unsupplied with water, George Stephenson caused it to be fastened in front of ours; moreover, a waggon laden with timber was also chained to us, and thus propelling the idle engine and dragging the loaded waggon which was beside it, and our own carriages full of people behind, this brave little she-dragon of ours flew on.”

—Melvin Smith

Source

John Pendleton, *Our Railways: Their Origin, Development, Incident and Romance*, Vol. 1 (London: Cassell, 1894), 64.

This surge of railway growth had its problems. It was ragged and uneven, much given to speculation that created a series of booms and busts, and lacked any form of standardization. From a technical standpoint, the latter problem was the most vexing. Aspiring engineers were working in largely unexplored territory as they experimented with locomotive configuration, rolling stock design, and track-building methods. Early railroads were a hodgepodge of differing gauges (the width between the rails) from line to line, which meant that anything traveling a long distance might have to be loaded and unloaded several times as it moved from one company's area to another. Standardized national gauges were soon developed.

Standardization became a key issue with the railroad. Before railroads, time was strictly a local affair; there was no need to synchronize clocks in London and Liverpool or in New York and Newark. Scheduling trains was crucial, however, both to maximize utilization of the rail line and to avoid horrendous accidents. As a result railroads adopted a standard time structure, first in Britain, which adopted Greenwich Mean Time as the national standard in December 1847. Time standardization came to North America in 1883 along with the concept of time zones due to the width of the continent.

Railroads not only standardized time but also changed the very concept of time and distance. “Near and far” took on new meanings as locomotives became faster and rail networks linked distant points. Journeys that would have taken days before the railroad became short trips measured in hours, with typical average speeds for long-haul trains ranging around 50 mph. This had the concrete effect of modifying the relationship between consumer and producer at all levels of the economy from raw material to finished product. Manufacturers gained access to supplies from increasingly distant sources and were able to market their wares to an increasingly broad segment of the national population. Farm surpluses found their way to larger markets as well, as did more exotic foodstuffs from foreign producers.

In a more abstract way the railroad could create a sense of national identity. While more people did travel greater distances, even people who never left home were affected. The railroad brought information of the greater world with it; newspapers, magazines, and catalogs reinforced the sense of being a part of a greater whole.

Railroad construction was a macroengineering proposal, an economy of scale. A typical rail of the 1880s weighed 80–100 pounds to the yard. This means that a mile of single track consumed between 140 and 176 tons of steel in rails alone. Between 1880 and 1890 American railroads laid 36,473 miles of new track, thus consuming somewhere between 5.1 million and 6.5 million tons of steel in that decade just to provide the rails. This figure did not include the steel needed for spikes, bridge plates, or the locomotives and cars themselves. In addition to steel, tons of gravel had to be quarried as ballast.

Forests of trees had to be converted into 8-foot-long cross ties. Tons of copper had to be drawn into wire for the telegraph to coordinate schedules. Thousands of workers had to be mobilized to create the components and thousands more to carry out the construction. Capital had to be raised to pay for it. In short, the construction of a railroad system required the construction of an industrial base.

Europe's Railway Network by World War I

In the period 1750 through 1914, Europe's railway network matured from horse-drawn tramways to steam-locomotive railroads. The extension of railways was inextricably tied to other aspects of the first and second Industrial Revolutions. Technological innovations, financing arrangements, military objectives, economic development, and cultural conditions were catalysts as well as beneficiaries of railroad development.

Technological innovations in Britain led the way for railway development. The transformation from tramways, operated with horse-drawn vehicles over wooden rails, to steam locomotion was a logical progression. Early privately owned tramways were often used to haul coal from mines. The first tramway charging tolls for public use, with users providing their own horse-drawn vehicles, was that of the Surrey Iron and Oystermouth tramway line, opened in England in 1803. The perfection of the steam engine by James Watt and others led to experimentation with steam-driven carriages. Richard

Trevithick's design of a blast pipe, allowing the simultaneous venting and drafting of a steam engine, was applied to what is generally regarded as the first steam locomotive. In 1804 Trevithick's locomotive—with one cylinder, a flywheel, and traction dependent upon the wheels against the tracks—carried 70 passengers and 10 tons of iron over a distance of 9 miles along the Penydarran Tramway in Wales. The heavy weight of this and other locomotives, however, required periodic and expensive track replacement. In 1811 John Blenkinsop, a coal mine operator, hired Matthew Murray to design a lighter locomotive with toothed wheels for traction; it operated with two cylinders, thereby obviating the need for a flywheel. The venture was a success.

George Stephenson and his son Robert were among the foremost designers of locomotives in England in the early nineteenth century. George was the surveyor and engineer of the Stockton and Darlington railway, also called the "Quakers' Line." Completed in 1825, it tied the port city of Stockton-on-Tees with the coal town of Darlington in England. Winner of the famous Rainhill locomotive trials in 1829, Robert Stephenson was the engineer of the 1830 Liverpool and Manchester railway, the first line to carry the royal mail. Subsequently, George and Robert Stephenson designed a 350-mile railroad network for Belgium. By 1886 Britain's railway network was extensive, totaling over 19,000 miles. The six largest lines accounted for nearly half of the total mileage: Great Western, Great Eastern, Great Northern, London & Northwestern, Midland, and North British.

The financing of European railways included private and state means. Private enterprise was the pattern in Britain. In 1839 Nicholas I of Russia sent officials on a fact-finding tour of railroads in Europe and the United States. Returning to Russia with a number of American experts, the delegation began construction of the Great Nicholas Railway between St. Petersburg and Moscow, opened in 1847. Later Alexander II of Russia pursued the development of railroads between the Baltic and Black seas. In France, a public-private partnership ensued. In 1842 the French National Assembly passed legislation for the construction of a rail network

radiating in seven great lines from Paris. The government agreed to defray the costs of the infrastructure (track bed, bridges, tunnels, etc.) for the railroads, while private enterprise laid the track, built stations and buildings, bought the locomotives and cars, and managed the operations. In Belgium the government initially financed the railway network, but later private financing assumed greater control. In some German states the government subsidized railroad construction, as occurred initially in Baden, Bavaria, Hannover, and Württemberg. Originally the Prussian state did not underwrite railroad construction, but after the 1848 revolution the government undertook a line between Berlin and Königsberg. The Austrian empire, with the financial support of the great banking families of Rothschild and Péreire, also pursued railway construction.

European powers realized the importance that railways could play in warfare. Prussia used railroads to transport troops and supplies to suppress a revolt in Polish Krakow in 1846. During the Crimean War (1854–1856), Great Britain was the first nation to build a military railroad. During the Austro-Prussian War of 1866 (also called the Seven Weeks' War) and the Franco-Prussian War, Prussia victoriously used railroads to deploy troops and supplies.

The construction, operation, and maintenance of railways were catalysts for many national economies. Although many nations initially relied upon the importation of locomotives and equipment from Britain and the United States, they often quickly developed their own factories for the production of rails and locomotives. Railways also served to connect source regions of raw materials with industrializing cities, leading to agglomerations of industry. For example, the Ekaterininsky Railway, completed in Russia in 1884, tied the iron mines of Krivoi Rog to the Donets coal district, contributing to the industrialization of the Ukraine. In Germany, the Ruhr River valley became another conglomeration of coal mines and the iron industry. Similarly, railroads proved important to the Italian industrial triangle of Genoa, Milan, and Turin. Although largely in the Asian section of Russia, the nearly 5,800-mile-long Trans-Siberian

Railway, connecting Moscow to Vladivostok, opened up settlement in Siberia. Economists have utilized interindustry structure to examine both the backward linkages (i.e., between railways and their suppliers) and the forward linkages (i.e., between railways and their customers) associated with railways. For example, railroads used coal, but they also counted coal mines among their transport customers. Likewise, while railways were purchasers of iron products, they conveyed both iron ore and finished iron products.

Political, military, and cultural conditions either influenced or dissuaded railway development. In the early years of railroad construction in Britain, for example, canal, road, and agrarian interests often opposed the approval of rail lines by Parliament. In France, followers of Saint-Simon viewed railways positively, while other Frenchmen denigrated them as aristocratic. As with any new technology, acceptance of railroads took time.

The World Almanac and Encyclopedia of 1914 noted, based on a 1912 report of the Prussian Ministry of Public Works, that Europe's railway mileage totaled 207,432 miles. Germany led Europe with 37,995 miles, followed by Russia's European mileage at 37,008 (not counting its Asian mileage). Third and fourth places were taken by France at 30,686 miles and Austria-Hungary at 27,570 miles. Great Britain held fifth place at 23,350 miles, followed by Italy, Spain (9,316 miles), Sweden (8,687 miles), Belgium (5,287 miles), and Switzerland (2,921 miles). The remaining nations had between 68 and 2,238 miles each. The largest percentages of state-owned railroads were Germany at 91 percent, Bulgaria at 89 percent, Romania at 88 percent, Italy at nearly 84 percent, Norway at 81 percent, and Austria-Hungary at about 80 percent.

Early Railways in India

Railroads for India were proposed initially in the mid-1830s. Fifteen years of promotion and debate ensued until key decisions in favor of the Great Indian Peninsula Railway (GIPR) and the East Indian Railway (EIR) were made in March 1849. Thus, finally, railroad building in Britain's largest imperial possession began in 1850. In 1853, the governor-general of India, Lord Dalhousie (in office 1848–1856), laid out a comprehensive plan for the development of the trunk lines.

Dalhousie's influential, lengthy memorandum—a “minute” in the language of the day—deserves close study. It provided justifications and guidelines for the system of railroads that was developed in South Asia under British auspices in the third quarter of the nineteenth century. The governor-general emphasized the political and military benefits railroads would provide. “Immeasurable” advantages would accrue to a colonial administration composed of a “comparative handful” of British administrators and soldiers scattered over the subcontinent. Railroads would enable Britain “to bring the main bulk of its military strength to bear upon any given point in as many days as it would now require months, and to an extent which at present is physically impossible.”

Dalhousie also noted the “commercial and social advantages” of railroads. These advantages included an increase in trade between India and Britain: more Indian “produce,” including raw cotton, would be transported to Britain, and more manufactured British goods would be sold in India. Railroads would encourage enterprise, multiply production, facilitate the discovery of latent resources, increase national wealth, and encourage “progress in social improvement”

similar to that which occurred in Europe and the United States of America.

The hardheaded Dalhousie stressed the political, military, and economic benefits accruing largely to Britain, to the Anglo-Indian connection, and to the colonial regime. He sought to influence calculating decision makers in London: his political masters, and also potential British investors from whom the bulk of the financing for India's railroads had to be obtained.

Thus, in the 1850s and for many decades, India's railroads were conceived and executed as a colonial project. British authorities, with little input from Indians, decided when and where lines would be built—and a good deal more. India's railroads were meant to serve British interests first and foremost, among which military and

➤ AN INDIAN CRITIQUE OF THE RAILROADS

Gandhi was not the only Indian who had reservations about the massive railway construction undertaken by the British. In 1884 V. J. Joshi, a schoolteacher and one of India's leading economic writers, bemoaned the lack of jobs provided by the railways for Indians. The following excerpt is from his article “The Economic Results of Free Trade and Railway Extension.”

“The railway establishments in all the higher grades are a closed preserve for the foreigner and even the lower duties of collecting or clipping tickets are entrusted to hands other than those of the natives of the country. A few native guards and drivers and fitters are all that the companies can show in the way of training the people for higher work and the position and status of these people are anything but comfortable. Everything for the people and nothing by the people [was said by Napoleon] . . . and in no country in the world has it been more vigorously carried out than in India, where the foreigner does everything for the people, who look upon all they see with rustic amazement.”

From V. J. Joshi, *Writings and Speeches* (Poona: Arya Bhushan, 1912), 688–689.

administrative security and economic benefits were central. The interests of Indians were incidental, although, as represented in the writings of Dalhousie and many Britons, the progressive consequences of the railroads for India were viewed as a self-evident truth. This assertion was accepted then as later by many Indians even though Gandhi wrote in *Hind Swaraj* (1921) about the railroads' contribution to the British control of India. Gandhi, in fact, went further. He denounced railroads as "evil" since "good travels at a snail's pace."

The template Dalhousie established in 1853 called for a system of great trunk lines best suited (1) to "maximize political and commercial advantages" along (2) specific routes providing favorable engineering conditions and (3) well situated for the subsequent construction of subordinate lines. First, Dalhousie advocated a line over 1,500 miles long heading north from Calcutta, then northwest up the Gangetic valley to Allahabad, on to Delhi, then deep into Punjab to Lahore, and onward to the Jhelum River. Second, he recommended two lines out of Bombay: one line in a northeasterly direction to tap cotton growing tracts in western India and to link up with the line in the Ganges valley, thus effectuating a through connection between Bombay and Calcutta; a second line to Poona and onward to the southeast to join up with a line built in a northwest direction from Madras. The latter junction required construction through the largest of the princely states ruled by the Nizam of Hyderabad, of whom, Dalhousie wrote, he "is a foreign potentate, but wholly helpless in our hands." Third, Dalhousie recommended the lines to be built outward from Madras. These were the northwest line just mentioned, and a line to the south, and then west through Coimbatore, and on to the west coast with a branch line to Bangalore (site of an important cantonment of British troops).

The period from the early 1850s to the early 1870s encompassed the pioneering two decades of railway building and operation in India. Many difficulties and hardships had to be overcome; many lessons, some involving considerable human or financial cost, had to be learned; triumphs great and small, and tragedies

with general consequences and/or individual loss occurred often. Great bridges were built and some fell down; thousands of construction workers died within days as gusts of epidemic diseases hit the assembled workforces; a young child laboring alongside his or her parents died because of an accident. Nonetheless, the engineers, contractors, colonial officials, skilled workers, and huge numbers of coolie laborers pressed on.

By 1861, 1,587 route miles of track were in operation and an additional 1,295 miles were under construction. The comparable figures in 1871 were 5,074 and 775. Estimates suggest that over a quarter of a million people were involved in railway construction in South Asia in 1861 with the total for the last half of the nineteenth century exceeding 10 million.

By 1871 the railroads had made a substantial impression on India and had become a prominent, new feature on the maps of the subcontinent. But their impression went far beyond cartographic representation. In the reporting year 1871, India's railroads employed 68,517 permanent employees, transported 19,283,000 passengers, and carried 3,542,000 net tons of goods. The railroads that reshaped India's landscapes also had considerable effects on India's society and economy.

Railways in Africa

Railways played a major role in European domination and exploitation of sub-Saharan Africa. Colonial powers built lines linking the coast and interior to consolidate territorial claims, support administration, and move troops to quell resistance. In the British colony, the Gold Coast, the line into Ashanti territory was built initially at the behest of mining interests but was also strategically important in connection with the later Ashanti Wars. In Nigeria the line into the interior was built primarily for strategic purposes but also promoted subsequent mining development. In East Africa the Germans and British built lines to the interior entirely for strategic reasons. As elsewhere, the often-expressed claim that railways would generate local traffic that would help the economy did not really mean much. Agriculture and general commerce did benefit from the railways, but particularly in the absence of mine-related traffic, railways could not sustain high enough freight charges to generate sufficient profits to achieve economic viability.

In southern and central Africa most lines were built primarily to support mining development, not so much to export the minerals as to import heavy machinery and supplies. Many of these lines were built by private companies rather than government. The greatest interest was aroused by Cape diamonds and Witwatersrand gold, but other areas subsequently attracted private investment, with returns on investment sometimes disappointing. Virtually all of these lines were direct links to seaports accessing European manufacturers and markets; no effort was made to create a transport infrastructure that could promote wider economic development. Such mining ventures were crucial to railway construction. The discovery of diamonds at Kimberley in 1866 led to the construction of a line from Cape Town. When the Witwatersrand gold fields opened in 1886, further links were created to Port Elizabeth and, largely due to political pressure, East London. Politics also resulted in another line through Natal to Durban. The Transvaal government resisted the entry of the Cape lines until the completion of the line through Mozambique to Lourenço Marques

➤ AFRICAN RAILWAY FANTASIES

The lure of mythical African wealth—Prester John, King Solomon, and Witwatersrand gold—led to many ideas for railways that bordered on the fantastic. The most famous was Cecil Rhodes's Cape-to-Cairo dream. Why anyone would have wanted to board a train in Cairo and emerge days later in Cape Town when they could have a much more comfortable journey by sea along either of Africa's coasts was never explained. The French talked of a Trans-African line to parallel the Cape-to-Cairo line and of a Trans-Saharan that would link Senegal to France's North African territories. The Portuguese also sought to tap into the diamond trade from the Rand and Kasai through lines from the Angolan coast into the interior, but the lines did not get very far. The lines that were completed fulfilled the strategic and economic interests of empire; no other lines made any sense.

—Simon Katzenellebogen

(present-day Maputo), the shortest route to the coast. The Portuguese only secured substantial traffic for the line by linking its use to the recruitment of Mozambican workers essential for the Rand gold and coal mines. By 1895 the mines were served by more lines than they needed.

The British South Africa Company (Chartered) financed the building of rail lines farther north: one from Beira, Mozambique, to Salisbury (present-day Harare) to tap gold fields that did not live up to expectations and then on to Bulawayo to connect with the second line coming north through Bechuanaland from the Cape. The line then went north to the Wankie coal fields and Victoria Falls and across the Zambesi River. After a delay, the line was extended to Broken Hill to serve the zinc and lead deposits. Because the zinc and lead ores could not be separated, this venture was not profitable, leaving the railway companies in serious financial difficulty. The South Africa Company reluctantly agreed to construct a line to the Katanga border where the Katanga Railway Company completed the link to the Katanga copper mines.

At Lobito Bay, Angola, another railway was to run via Benguela to the Katanga border (only

completed in 1928) and then on to the mines. This line was in theory the most economical line for Katanga copper but has never been used to its full potential. The Belgians preferred to serve their own purposes by using the Bas-Congo to Katanga line to Kasai, then going by water and rail to the coast. The line via Wankie to Beira continued to carry substantial amounts of traffic as part of arrangements to ensure coal supplies for smelting. After World War I when technological developments made it possible to exploit the Northern Rhodesian Copperbelt sulfide deposits, only a short length of line was needed, and sub-Saharan Africa's railway system was essentially in place.

After African independence from colonial powers, additions were made to the system, but no real effort was made to create an infrastructure integrating African's economy. The most spectacular failure was the line linking the Zambian railways to Dar es Salaam on the Tanzanian coast. Built with Chinese help but paid for entirely by Zambia, the line proved totally inadequate for all-season heavy traffic. The imperial rail system continues to reflect European dominance of African interests.

Railways in Russia

Russia's enormous size, harsh climate, and diverse terrain long made transportation a pressing concern for its government and people. Yet prior to the mid-1830s, there were no railways to help bridge Russia's vast distances except for a few horse- and steam-powered mine and factory

lines. Goods and passengers traveled by horse-drawn carts and sledges, barges, and boats; in winter, frozen rivers and lakes served as temporary roads. But rapids, shallows, and ice hindered water transport, and some areas lacked usable rivers; major roads were scarce, rarely paved, often in poor repair, and impassable seas of mud during the spring thaw. This slow, unreliable, and expensive transport system hindered economic development.

Russia entered the railway age under Tsar Nicholas I (r. 1825–1855). Although a reactionary and repressive ruler whose fear of revolution led him to stifle Russian social and intellectual life, the tsar was open to new technology that might enhance Russia's economic and military strength. Thus, overriding Minister of Finance Egor Kankrin's (1774–1845) objections that railways would waste public funds, endanger carters' and barge-haulers' livelihoods, and encourage social instability by increasing the population's mobility, in March 1836 Nicholas authorized the Austrian engineer Franz Anton von Gerstner (1793–1843) to construct Russia's first railway, a 17-mile (27-kilometer) line between St. Petersburg and Tsarskoe Selo, which housed one of the royal palaces and many noblemen's summer residences. When the railway opened on October 30, 1837, eight carloads of curious passengers made the 28-minute one-way journey from the capital.

Subsequently, Nicholas I ordered the construction of a 403-mile-long line between St. Petersburg and Moscow (1843–1851), and in 1852 work began on lines connecting Warsaw in Russian-ruled Poland with St. Petersburg and Vienna. Yet by 1855 only 653 miles of track had been laid (less than one-tenth the length of Great Britain's rail network at the time). Most rails had to be imported since the few Russian factories capable of producing them lay far from the construction sites and since Russian engine and car production was still in its infancy. These shortcomings helped ensure Russia's defeat by Britain, France, and the Ottoman empire in the Crimean War (1853–1856) since Russia could not move men and equipment to the front by land as quickly as its enemies could by sea.

The defeat in the Crimean War highlighted Russia's economic, military, and social

backwardness, and the next ruler, Alexander II (r. 1855–1881), launched a reform program that emancipated the serfs and modernized Russia's military, administration, schools, and courts. At the same time, he encouraged entrepreneurs to expand Russia's railways. By the end of his reign, Russia boasted 14,544 miles (23,406 kilometers) of track and more factories to produce engines, cars, and rails. But the generous contracts he awarded to railway firms were enormously expensive (railway costs were one factor behind Russia's sale of Alaska to the United States in 1867), while lax oversight and the state's guarantee of their profits discouraged cost effectiveness; private railroads owed the state over 1 billion rubles by 1880! Consequently, Russia's railways and industry still lagged behind the rest of Europe (as shown in the 1877–1878 Russo-Turkish War, in which railway bottlenecks slowed down troop movements).

To remedy these problems, the state took a more active role in railroads under Alexander III (r. 1881–1894) and Nicholas II (r. 1894–1917), whose reigns saw the climax of Russian railway expansion. In the early 1890s, Finance Minister Sergei Witte (1849–1915) launched an ambitious campaign of rapid industrialization in which railway expansion, especially in Siberia, played a key part.

By the eve of World War I, the Russian empire's railways had 48,600 miles of track, 16,234 freight and 3,823 passenger engines, 475,000 freight and 31,000 passenger cars, and 815,500 railway workers. Railroads annually carried 158 million tons of freight and handled 144 million passenger journeys. Despite these achievements, fuel shortages, equipment failure, transportation bottlenecks, and the deterioration of rolling stock hampered the Russian war effort and played a major role in Russia's generally poor performance in World War I, thereby helping to set the stage for the monarchy's collapse in 1917.

THE TRANS-SIBERIAN RAILROAD

Siberia holds over 5 million square miles (13 million square kilometers) of Russian territory. Rich in minerals, coal, oil, and timber, in the late nineteenth century Siberia lay dangerously close to a powerful Japan. Yet beyond a few minor railroads in western Siberia, only rivers and a rough postal road linked it to the center. Building a railway here was a vital economic, military, and political necessity. Thus, on May 19, 1891, the future Nicholas II ceremonially dug a shovelful of earth in the Pacific port of Vladivostok, officially commencing the Trans-Siberian Railroad's construction.

Stretching 5,500 miles (8,850 kilometers) from the Urals to Vladivostok, the Trans-Siberian was the world's longest railroad. Over 70,000 men had to lay tracks across forests, swamps, mountains, gorges, and rivers (over 50 bridges crossed the Angara River alone) and ram pilings deep into permafrost. By the fall of 1900 most of the line was in operation, but tracks through rugged terrain along Lake Baikal and the Amur River were not completed until 1904 and 1916.

Railways in North America

Railway construction began in North America at the end of the 1820s, a time when most of the population and industry were concentrated on or near the Atlantic coast. Railways had a dramatic impact on the continent, facilitating the

JAMES J. HILL

Born in Upper Canada, James J. Hill (1838–1916) moved to St. Paul, Minnesota, at the age of 18. After being involved in the steamboat business, the coal business, and banking, he bought the St. Paul and Pacific Railway in 1873, operating it with Donald Smith and George Stephen, both of whom were to later play vital roles in the Canadian Pacific Railway. In 1879 Hill formed the St. Paul, Minneapolis, and Manitoba Railway, which expanded significantly in Minnesota, Manitoba, and Dakota Territory during the 1880s. It was renamed the Great Northern Railway, and Hill extended it across the continent to the Pacific. The Great Northern was the only American transcontinental railway built without public money or land grants and would be the only such railway not to go bankrupt.

—*Wesley Ferris*

settlement of the interior and the expansion of industry and trade. By the early twentieth century, the rail network in the United States had grown to be the largest national rail network in the world, while in Canada railways had played a vital role in the unification of the country.

The first interest in railways in the United States was in those cities that lacked other clear transportation links such as rivers or canal networks to the growing interior. Thus, one of the first railways in the United States, the Baltimore and Ohio, was formed by leading merchants and bankers in Baltimore and had linked to Harpers Ferry and Washington, D.C., by the late 1830s. Railway construction quickly began in other major cities, and by 1840 there were over 2,800 miles of track in 22 of the 26 states then in the Union. Construction continued to accelerate, with a particular focus on connecting to the city of Chicago, which in the 1850s became a central hub of the railway network in the old Northwest. By 1860 there were over 30,000 miles of track, and the fact that less than a third of this mileage was in the South was a decided advantage for the North in the American Civil War (1861–1865).

After the Civil War, a major focus of railway construction was the completion of a

transcontinental railway, linking the Pacific coast with the Atlantic. The Pacific Railway Act (1862) formed the basis of the construction of these lines, which included generous land grants and government loans. The first transcontinental railway was constructed by two companies: the Central Pacific, building eastward from Sacramento, California, and the Union Pacific, building westward from Omaha, Nebraska. The two railways met at Promontory Summit, Utah, in 1869, linking east and west. In the years that followed other transcontinental railways were completed, including the Northern Pacific, the Great Northern, the Southern Pacific, and the Atchison, Topeka, and Santa Fe. Rapid railway expansion continued in the late nineteenth century. By 1870 there were 52,900 miles of track, increasing to 93,200 miles by 1880. Expansion continued until the American rail network reached its maximum mileage of just over 250,000 in 1916.

Railways transformed the United States. They facilitated the settlement of the American West while also contributing to the decline of the Native American peoples west of the Mississippi River. Railways drastically reduced transportation time and were a crucial component of the rapid industrialization of the United States, particularly after the Civil War. The coming of the railway was not, however, without difficulty. Railway companies were often financially hazardous enterprises, and cut-throat competition often existed between different companies serving the same cities. The failure of the banker and railway financier Jay Cooke triggered a national economic crisis that became the Panic of 1873, while the Panic of 1893 resulted in bankruptcy for a quarter of the railways in the United States. Indeed, all but one of the great transcontinental railways had gone bankrupt at some point by the end of the nineteenth century. By 1906, mergers and acquisitions, particularly of bankrupt railways, led to a situation in which two-thirds of the American rail network belonged to seven groups. Railway workers also began to organize in the late nineteenth century, and management-labor confrontations such as the Railroad Strike of 1877 increased. Many farmers who lived in the

American West criticized the rates charged by railways, and their discontent played a leading part in the rise of the Grange movement. Such criticisms also resulted in the creation of the Interstate Commerce Commission in 1887 to regulate railways, which were also often a target for antitrust legislation.

The first railway in Canada, the Champlain and St. Lawrence Railway, was completed outside Montreal in 1836, but significant railway growth did not begin until the 1850s. Railway construction rapidly escalated through the 1850s in Upper and Lower Canada, including the completion of the Grand Trunk Railway. Railways were to play a critical role in the political unification of Canada. New Brunswick and Nova Scotia were encouraged to join the Confederation in 1867 with the promise of a railway, eventually the Intercolonial Railway, linking them to Ontario and Quebec. British Columbia was promised a transcontinental railway in 1871 as part of its decision to join Canada. After several fitful starts and the Pacific Scandal of 1873, which saw the collapse of the Conservative government, the Canadian Pacific Railway began construction in 1881 and was completed by 1885. The Canadian Pacific opened up the Canadian West to large-scale migration and became one of the largest and most influential companies in the country. Later efforts at transcontinental railways in Canada were undertaken by the Canadian Northern and Grand Trunk Pacific railways, but financial difficulties caused by World War I forced their acquisition by the Canadian government and merger into the Canadian National Railway in 1923.

Railways in Latin America

The first railroad in Latin America was built in Cuba in 1837. Railroad development began in South America with the first railroad line in Chile in 1852. The Panama Railroad, financed by North Americans led by William Henry Aspinwall (1807–1875), the founder and president of the Pacific Mail Steamship Company, was completed in 1855, linking the Atlantic and Pacific oceans across the Isthmus of Panama. Railroad construction was initially hampered by chronic political instability and limited capital. By 1914, however, Latin America had approximately 51,726 miles of railways, with most concentrated in four nations: Argentina, with 19,796 miles; Mexico, with 15,907 miles; Brazil, with 15,370 miles; and Chile, with 5,013 miles. Colombia and Venezuela had only just over 600 miles of track, a major impediment to economic growth. In the Caribbean region, Cuba had the largest rail network, with 2,331 miles, while in Central America, Guatemala had the largest network, with 613 miles.

Railroad expansion had its most profound impact on the open pampas of Argentina. Using British capital, lines spread out from Buenos Aires into the hinterland. As was also the practice in the United States in the same era, the Argentine government helped ensure profitability by granting the railroads lands along the roadbeds. By 1880 Argentina had just over 6,000 miles of track, an increase from 24 miles in 1860. In 1876 Argentine beef began to be shipped to Europe aboard refrigerated cargo vessels, and meatpacking soon became a booming industry. Argentina became an economic colony of Britain and, to a lesser extent, France, providing meat, grain, and leather in exchange for manufactured goods. But Argentina witnessed a growth rate of 5 percent a year from the 1870s to 1914, to which the railroad made a major contribution. Only in 1948 did Argentina purchase its railway system from its British and French owners, at a price of \$600 million.

Mexico was another country in which railroads played a significant economic role. Plans to introduce railroads began in the 1830s, when the government granted a concession to build a

➤ RAILROAD CONSTRUCTION IN LATIN AMERICA—RISKS AND CHALLENGES

Besides the usual financial risks of building railroads in Latin America in the late nineteenth century, terrain and climate often presented unique challenges. The mortality rate for workers was high. In building the 50 miles (80 kilometers) of the Panama Railroad in the 1850s, for example, it is estimated that over 6,000 workers died, mostly from yellow fever and cholera. Supposedly some of the corpses were preserved and sold by the Panama Railway company to medical schools and research hospitals, and the income was used to pay for the company's hospital, where workers

were treated. Seven thousand workers died constructing the Central Railroad in the Peruvian Andes, where altitudes rose 15,000 feet (4,572 meters) in 78 miles (126 kilometers), requiring endless V-shaped switchbacks to keep grades to a manageable 4 percent. On the Arequipa-Mollendo line in Peru, engineers had to construct an 85-mile (137-kilometer) pipeline just to bring the water needed for the locomotive steam engines down to Mollendo on the waterless desert coast.

—Timothy Neeno

line between Mexico City and Veracruz on the Gulf of Mexico. Political instability and lack of capital, however, delayed the beginning of work on the project until 1864, when under the rule of Emperor Maximilian the Imperial Mexican Railway Company began construction. After a decade, in 1873, the Veracruz-to-Mexico City line was inaugurated as part of a plan to build a railway from Veracruz through Mexico City and then to the Pacific coast. President Sebastián Lerdo de Tejada and his successor Porfirio Díaz both strongly supported railway construction, which they encouraged through land concessions and government subsidies. During the long period of relative political stability under Díaz, American, French, and mainly British investors provided capital for railway projects. Railroads fueled the development of northern Mexico, allowing the development of copper, zinc, and lead mines. Silver exports jumped by 150 percent between 1876 and 1910, during which time Mexico maintained an annual growth rate of 8 percent.

In Brazil the first railroad line was constructed in 1854 from Rio de Janeiro to the imperial mountain resort of Petropolis, a distance of approximately 40 miles. But it was coffee and sugar plantations that encouraged the flow of British capital. In 1874 Brazil had just 800 miles of track. By 1889 it had 6,000 miles of track, linking 14 out of 20 provinces. By World War I

there were 16,000 miles of railroads. Development remained uneven. More than half the mileage was in the three southeastern states of São Paulo, Minas Gerais, and Rio de Janeiro. The São Paulo to Santos line was wildly profitable due to its monopoly on transport from the main coffee plantations. It yielded annual dividends of 50 percent on a regular basis. By 1910 Brazil was producing 77 percent of the world's coffee.

In Brazil in particular but also in many other Latin American countries, railroad development centered on the movement of crops and raw materials from interior regions to coastal cities for export. Hence, railroads tended to reinforce the region's dependence on export specialization rather than encourage diversification. There is no question, however, that railroads contributed to overall economic growth. Towns and villages sprang up along rail lines. Railroad construction and development fed the growth of a skilled labor force and an educated middle class. Workers in once-isolated rural areas could more easily seek jobs in cities. At the same time, corporate-government connections led to corruption, and foreign ownership of the rails led to increased economic dependency.

New Ships for Ocean Travel

During the two centuries before the Industrial Revolution, ocean transport had been carried on by wooden sailing ships that usually had a length of 100 feet or less and rarely exceeded 200 feet. They carried approximately 100 tons of cargo and had crews of 20 to 30 men. Ownership of these ships usually was divided into fractional shares: one-half, one-quarter, one-sixteenth, and so on. These shares were usually owned by individual merchants or partnerships of merchants, with a minority share of ownership frequently held by the ship's captain and officers. Most of the cargo space was devoted to the merchant-owners' goods, and any unused space was rented out to other merchants. Ships sailed when their holds were filled, with no scheduled arrival or departure dates and few set routes.

Most ocean transport was concentrated in the North Atlantic, either between European coastal nations or between Europe and the American colonies. European nations also carried on a smaller amount of waterborne trade with Africa, the Middle East, and Asia. Non-European empires and states had few seafaring vessels, mostly concentrated in the coastal states bordering the Indian Ocean.

The first technological innovation of water transport resulting from the Industrial Revolution was the adaptation of steam engines for propulsion. Initially, steamboats ran only on the inland waters of rivers, lakes, and canals. By the 1820s and 1830s, however, steamships were beginning to cross the Atlantic. Transatlantic voyages of sailing ships took between three weeks and three months, depending on winds and weather. Coal-burning steamships

could make the voyage in two weeks. Further advances in steam-engine technology and the adoption of the screw propeller in place of wooden paddles increased steamships' speed and shortened the crossing time by the late 1800s to less than a week.

During the mid-1800s, advances in metallurgy led to the replacement of ships' wooden hulls with iron and later steel. Metal was more expensive than wood and required more energy-intensive methods of preparation, but metal ships were more durable and safer. Metal ship construction also led to the construction of much larger ships. The largest possible wooden ship was 300 feet in length, as a result of structural weaknesses caused by the pounding of waves. Ships constructed of iron and steel, however, could withstand the impact of waves, so there was no structural limit upon their size. By the late 1800s, the largest metal steamships were nearly 1,000 feet (305 meters) long.

The Industrial Revolution also fostered a new type of business organization, the shipping line. The increased costs of constructing and

➤ CUNARD SHIPPING LINE

In 1840 Samuel Cunard (1787–1865) launched the *R.M.S. Britannica* from Glasgow, Scotland, beginning the Cunard shipping line. The *Britannica*, primarily a ship for carrying mail between Liverpool and Halifax, Nova Scotia, was a hybrid of sail and steam like most of the Cunard ships built until the 1890s. The ship's success was followed by other Cunard ships, including the *Caledonia* (1840–1851), the *Hibernia* (1843–1868), the *Persia* (1856–1872), the *Russia* (1867–1902), and many more that grew in luxury to appeal to wealthy travelers. Many of these ships also carried cargo as well as immigrants (from 1860–1900), and as British-owned ships were pressed into wartime service as troop transports. In 1893 the *Campania* (1893–1918) and the *Lucania* (1893–1909) were launched. These two luxury liners were “wonder ships.” They were the first of the Cunard ocean liners to be screw-propelled without any sails, crossing the Atlantic in six to seven days.

—Jack Waskey

running steamships were beyond the capacity of any single merchant or partnership. This led to the creation of corporations that specialized in owning and operating steamships. The competitive advantage of providing frequent service caused these firms to acquire multiple steamships, allowing several departures each week for major seaports. This increased the shipping lines' need for capital investment and eventually led to the consolidation of most of the industry into a small number of large firms.

Most of the large shipping lines were British and had started operations during the 1830s and 1840s. Samuel Cunard pioneered steamer service between Britain, Canada, and the United States, and his Cunard Line soon dominated North Atlantic routes. Its major British competitor was the White Star Line, owner of the *Titanic*. The Peninsular and Orient Navigation Company (P&O) became a major line on routes to the Middle East, Asia, and Australia. Most other industrial nations soon developed major shipping lines, frequently using subsidies for carrying the mail and other forms of government assistance. France had *Compagnie Generale Transatlantique* (also known as the French Line), the Netherlands had the Holland America Line, and Germany had the Hamburg America Line. The latter had the largest number of ships (126) in 1910.

The United States was the only industrial nation without a major shipping line. High labor costs and other factors led the nation's investors and entrepreneurs interested in transportation to focus upon railroad companies and continental land development rather than international shipping. U.S. shipping lines either focused upon the nation's coastal trade, which was limited by law to U.S. ships manned by U.S. crews, or were adjuncts of larger corporations such as the United Fruit Company.

The Japanese government gave a high priority to the development of steamships and shipping lines after the Meiji Restoration. The government fostered the consolidation of smaller lines into the Japan Mail Steamship Company in 1885. This line soon expanded its operations to seaports in India and then to Europe and the United States in the 1890s.

The development of metal steamships resulted in a steady decline in the cost of ocean shipping and an accompanying growth in the volume of waterborne international trade. By the end of the century, the annual volume of international trade (most of which was carried by ships) was nearly twenty times greater than at the beginning of the century. This in turn facilitated the growth of factories and other aspects of industrialization in Britain, northwestern Europe, and North America by bringing raw materials to industrialized nations and taking manufactured products to less developed regions.

In addition to their economic impact, advances in ocean transport played a key role in many other significant developments in the nineteenth century. They include late-nineteenth-century imperialism, large-scale migrations, military planning, the spread of diseases, and increasing cultural interaction among the world's peoples.

Canal Building in Asia

The nineteenth century saw significant canal building projects in Asia as colonial powers attempted to increase agricultural productivity and exploit the ability of canals to transport goods. Large-scale canal building was not a new phenomenon in Asia. The oldest sections of China's Grand Canal, which today links Hangzhou and Beijing, date back to the fifth century BCE; the Ling Qu Canal, which links the Xang and Lijiang rivers, was begun in the third century BCE. In addition, irrigation canal works were widely used by farmers throughout Asia long before 1750. Nineteenth-century canal projects, however, were notable for their scale, their connections to colonialism, and their use of technical knowledge developed during Europe's eighteenth-century canal-building boom.

In 1750 China's Grand Canal was Asia's most significant canal, connecting China's agricultural south with its northern cities. The canal ran roughly north-south and connected China's major rivers, which tend to run west to east. In 1793 George Macartney, the British envoy sent to China to negotiate a new trade treaty with the Qianlong emperor in Beijing, spent 72 days traveling the 1,096-mile length of the canal, some sections of which were already 2,000 years old. However, the canal was in decline despite concerted government efforts to maintain it. Because of problems of erosion and siltation around the region of the Yellow River, the canal became unusable for large boats; some sections were completely impassable. These problems also caused damage to the canal's infrastructure, such as dykes. In 1855 the Yellow River completed one of its periodic shifts in course, abandoning its previous delta and connections with the Grand Canal. From 1878 food traveled by sea rather than the Grand Canal, and in 1899, 8.4 miles of the canal south of the Yangtze was dry for a period of four months. Thus, in China a significant canal system was ruined, and goods that had been transported by inland waterway shifted to sea transport.

Elsewhere in Asia increasing contact with Europe led to increased canal building. In Sri Lanka the Dutch East India Company completed

CHINA'S GRAND CANAL

The Grand Canal of China was well established by the time George Earl of Macartney spent 72 days traveling down it in 1793. Macartney was returning from an unsuccessful diplomatic mission to Beijing, and his party consisted of 40 vessels and about 1,000 people.

While the length of the canal (1,096 miles, or 1,764 kilometers) and its age were impressive, its technology was not. Locks consisted of granite-sided sections with wooden planks placed across the canal to maintain a difference in water level. When boats needed to pass, the planks were removed; the release of water swept the boats downstream. The uncontrolled rush of water was difficult to navigate, and vessels were likely to be damaged. Similarly, slipways where the canal joined rivers made navigation difficult. Bridges across the canal were low and had steps at either end. Boats had to lower their masts to pass beneath, and wheeled transport could not cross above. Macartney's boats were powered by men walking along a path beside the canal. Furthermore, Macartney's voyage was troubled by low water levels: ongoing siltation continued to reduce the usefulness of the Grand Canal.

—Claire Brennan

significant canal construction near the west coast of the island by 1795. Earlier indigenous irrigation work was extended and improved upon by the Dutch. Once they overcame difficulties of dealing with the infiltration of seawater, the new canal structures provided both irrigation and transport. Later the British maintained the system established by the Dutch and extended the system of canals around the capital, Colombo.

In India and Indochina, European colonial powers undertook various irrigation projects. French colonial rule in Vietnam led to the planning and construction of several canal projects after 1894. In Java the Dutch extended and improved preexisting indigenous irrigation networks with the introduction of the Cultivation System in the 1830s. But irrigation works developed haphazardly until the General Irrigation

Plan for Java was completed in 1890. This plan included 19 different projects that would cover close to 990,000 acres, most of which were complete by 1920.

Neither the French nor the Dutch could equal the British in terms of canal building. During the nineteenth century British army engineers constructed the largest artificial irrigation system in the world at the time in northern India. Between 1817 and 1901, 3,407 miles of main channel and 18,195 miles of smaller channels were constructed, first by the British army and then by the Public Works Department established in 1854. The main channels of British irrigation works also could serve as waterways for boats, but the smaller channels only distributed water to rice paddies and other agricultural land. The Upper Ganga irrigation project was completed between 1836 and 1854, while the over 3.7 million-acre Indus Valley irrigation project was completed in 1849. There were also large-scale developments in other river deltas such as the Krishna, Godavari, and Cauvery from the middle of the nineteenth century onward. This period of canal building was not without its problems. Engineers often failed to design drainage systems for irrigation water, and this in turn caused environmental problems in irrigated areas such as waterlogging and salination.

Some European and American canal-building technology was adopted by Asian engineers. In Thailand, which had canals for centuries, Thai engineers designed and built European-style locks from 1890 onward. The canalization of the Young Delta of the Chao Phraya from the middle of the nineteenth century created a new transport route, new arable land, and a reliable water supply. As a result of such irrigation projects, Thailand's rice exports increased from 120,000 tons in 1870 to 1.5 million tons in 1929. In Japan, canals were built following North American models. Sakuro Tanabe, engineer of the Biwako canal, was inspired by a visit to the United States, particularly to a hydroelectric plant in Aspen, Colorado. The Biwako canal was built to supply Kyoto with water from Lake Biwa and also acted as a means of transport and electricity generation. The canal, completed in 1894, is 6.8 miles in length and includes a roughly 22-mile change in height.

In 1750 Asia already had a significant number of canals, but further networks were developed as changes in colonial policy led to extensive canal works in some parts of Asia during the late nineteenth century. As a result of European colonial involvement some existing canal systems were extended, and techniques for water control and canal building were exported from Europe and North America to Asia. However, irrigation tended to predominate over transportation in the building of Asian canals, and the Grand Canal of China stagnated rather than prospered.

Canal Building in Europe

The years after 1750 saw a significant burst of canal building, first in Britain and then across Europe, as Dutch engineering techniques spread and industrialization created new demand for cheap and reliable ways to move raw materials and finished products. For centuries Europeans had been altering the course of rivers to aid transport. Such alterations usually involved straightening the course of a river or deepening it to help the passage of boats. The process was known as canalization, and the waterways created were often referred to as navigations.

The completion of the Bridgewater Canal, designed and constructed to carry coal from

the estate of the third Earl of Bridgewater to the industrial center of Manchester (completed in 1761), marked the beginning of a new phase of canal construction involving completely artificial waterways. This canal defied a river's need to flow from source to ocean, lake, or another stream. It did this by staying at the same height for all its length, including the use of an aqueduct to cross nearly 39.3 feet above the Irwell River and tunneling to carry it directly into the duke's coal mine. It also included a tow path—a canal boat was typically powered by a horse walking alongside the canal and was pushed through tunnels by men lying on their backs on the boat and “walking” along the tunnel walls, a process called “legging.”

The success of the Bridgewater Canal in moving coal directly from mine to city inspired a boom in the building of privately financed canals that lasted until 1790. To reduce the cost of construction, these canals were narrow and no longer than absolutely necessary to transport the products of mines to market. They were owned and built by landowners with mineral resources on their estates, and they supplied the mills and factories of the Industrial Revolution with their raw materials in the form of coal and minerals. By 1790 a system of small privately built canals covered much of Britain, and the so-called Silver Cross of natural and artificial waterways linked the mouths of the four large rivers—the Mersey, Humber, Thames, and Severn—that carried shipping deep into southern Britain. A second canal-building boom overlapped the first, starting in 1789 and ending in 1798, as larger canal works were undertaken by companies financed by the public sale of shares. In 1760 England and Wales had contained 1,483.2 miles of inland waterways (mostly rivers). By 1790 there were 2,310.2 miles, and by 1810 there were 3,999.7 miles. Early canals were extremely energy-efficient and easier to build and maintain than networks of high-quality roads, but canal transport was slow, and in Britain the coming of the railway with its promise of cheap and speedy inland transport ended the era of canal-building booms. Ship canals were still built to allow large oceangoing vessels to reach inland ports, but internal transportation came to rely on roads and rail rather than water.

➤ KEEPING WATER IN CANALS

Canals need to contain water to be useful, but because they are unnatural waterways, water tends to seep away into the surrounding soil, particularly where canals lie above ground level.

In Britain in the 1700s the most common way to watertight a canal was puddling, lining the canal with clay that was then trampled by livestock, forming a watertight barrier. This method was also used with aqueducts, requiring them to hold 3–4 feet of clay as well as water. As early as 1796 iron was beginning to be used in the construction of canal channels and aqueducts, and thus seemingly shallower aqueducts were able to contain a greater depth of water, as the iron was watertight without clay.

In France, canals and aqueducts had continued to be constructed using hydraulic cement, which was able to harden while underwater. This material had been widely used by Roman engineers, but elsewhere in Europe its use had been lost. The development of Portland cement in 1824 made concrete widely available. By the early twentieth century concrete was used to waterproof canal channels, and reinforced concrete had become the standard material for constructing canal aqueducts.

—*Claire Brennan*

The canal-building boom had allowed British engineers to develop expertise in moving ships from one level of water to another and develop improved locks, sluices, weirs, and lifts. This expertise was then exported to other regions of Europe (and North America) as ship canals were built there. France, Spain, Prussia, and Russia all created state-controlled canal networks, although the French Revolution and its aftermath delayed canal building in France. Sweden, Denmark, Finland, Bavaria, and the Netherlands all participated in the new European enthusiasm for canal building to a lesser degree. In Europe, the limitations of the early narrow British waterways were recognized, and continental canals were wider than those of Britain because they provided secure inland routes that allowed seagoing vessels to avoid hostile navies and bad weather. For example, the Kiel Canal in Germany, completed in 1895, carried warships from the Baltic Sea to the

North Sea. The significance of European ship canals for oceangoing vessels protected them from direct competition with railways. The connection of canal building to the Industrial Revolution resulted in new economic opportunities and social change as a result of those opportunities. The new network of canals forged connections between cities and their hinterlands and between ocean basins and provided pathways for ocean shipping to reach inland ports.

North American Canals of the 1800s

The original purpose for canal building was to make water transport of freight possible in areas where land transport was difficult and slow. For example, in the late eighteenth century, the transport of goods weighing 1.5 tons from Philadelphia to Pittsburgh (350 miles) could take up to a month. However, by linking natural waterways—the St. Lawrence, Hudson, Ohio, Illinois, and Mississippi rivers and the Great Lakes with canals, the movement of freight was more predictable, and faster; it made possible the economic development of previously inaccessible places in the Midwest. In 1845, before Chicago was connected with the Illinois River (a tributary of the Mississippi) by canal, it was a small town with fewer than 200 inhabitants but grew rapidly after the canal was completed. New York City was also a beneficiary of improved trading links because the Erie Canal, completed in 1825, linked Buffalo on Lake Erie with Albany on the Hudson River, allowing goods from Midwest farms to be transported cheaply and efficiently to New York.

Since the time of the early explorers, water routes were sought to the sea or for further trading opportunities. The St. Lawrence River caused difficulties for travelers because of blockages in the form of rapids and waterfalls. To deal with this problem, the Lachine Canal was completed in 1824 in the city of Montreal, Canada to allow ships to travel from the Atlantic to the Great Lakes. While the canal is just under 9 miles long, it rises a total of 50 feet. Other canals were built to cope with the different obstacles. New developments included the Soulanges Canal (1899), Beauharnois Canal (1845), Cornwall Canal (1842), and finally the Rideau Canal (1832) between Ottawa and Kingston. Further west the Welland Canal was constructed to provide a route to avoid Niagara Falls. Built between 1824 and 1833, it is 27 miles long and rises 326 feet by means of locks.

Financing for canal building was generated from state government, the federal government, and private investors. The Erie Canal was built with \$7 million from the state of New York. The Chesapeake and Cumberland Canal, which linked the waters of the Delaware River with those of Chesapeake Bay when it opened in 1829, was financed by the states of Pennsylvania (\$100,000), Maryland (\$50,000), Delaware (\$25,000), the U.S. government (\$450,000), and the remainder from private investors.

When facing challenging terrain and the demand for more efficient transportation, the availability of funding encouraged engineers to be innovative. Most notable was the Sandy and Beaver Canal in Ohio. Privately financed by the Sandy and Beaver Canal Company, and completed in 1848, it operated for only four years, but is notable for its canal engineering, including the Big Tunnel, the longest canal tunnel in America—1,060 yards blasted out of solid rock. It also has another tunnel through hard shale and coal. Another engineering marvel is the connection between Philadelphia and Pittsburgh, built in response to New York's Erie Canal, which was weakening Philadelphia's standing as the leading U.S. port. In eight years, Pennsylvania state canals were combined with a 36-mile portage railroad using steam-operated inclines, which resulted in the opening of 394 miles of Main Line in 1834.

While canals were often built for access and trading routes, they were also built to harness vital water supplies. The building of the Chicago Sanitary and Ship Canal in 1887 was motivated by a health crisis from polluted waters in Lake Michigan. Chicago's chief engineer decided to cut through a ridge between the lake and the Mississippi River; a canal 28 miles long was built that reversed the flow of the Chicago River. By controlling the flow with locks, Chicago gained control of the draining wastes from its northern suburban communities.

By 1850 the burgeoning canal network in North America faced competition from the railway, and the boom in canal construction ended. The New York State Barge Canal, which replaced the Erie Canal in 1918, was the one exception. While some canals have gained a new life, there are those that suffered a quick demise. The Alexandria Canal linked Alexandria, Virginia and Washington D.C. when it opened in 1843, but its operations came to an end in 1886. An example of new life for a canal is provided by the Whitewater Canal, which runs from Lawrenceburg, Indiana on the Ohio River upstream to Hagerstown, Indiana, 76 miles in length. It was closed and sold to a railroad in 1866, but there is a remaining small section now restored for boat trips. The recreational use of canals is in evidence elsewhere as well. The Dismal Swamp Canal, built between 1793 and 1805, joined the Elizabeth River near Norfolk, Virginia to the Pasquotank River in North Carolina. It originally took logs from the swamp, but is now a recreational waterway for viewing wildlife.

Official recognition of the role that canals have played in the history of the infrastructure of North America has been given to canals such as the Delaware Canal, which was part of the canal system linking Pittsburgh and Philadelphia, running 60 miles in length between Bristol and Easton, Pennsylvania. It was completed in 1832, and with a fall of 165 feet, it required 23 locks. The canal was used to transport coal from the northeast to the cities in the east, with over a million tons of coal a year moved on this route prior to the Civil War. Traffic declined and the last paying boat was in 1931. However, the canal was designated as a National Historic Landmark

in 1978, resulting in the best preserved towpath canal in America.

Recreational waterways, like the Trent-Severn Waterway, is a river-lake-canal route from Trenton, Lake Ontario to Port Severn, Georgian Bay, Lake Huron. While it was started in 1833, and built to carry lumber, settlers and freight crossed central Ontario with 36 conventional locks, two staircase or flight locks, two hydraulic lifts or lift locks, and a marine railway. It is now a 240-mile cruising route that has grown in popularity after an enthusiast's society was started in 1982.

Canal Building—The Suez Canal

The French invasion of Egypt in 1798 and the increase in European-Asian trade in the nineteenth century sparked new interest in a canal linking the Mediterranean Sea and the Indian Ocean by way of the Red Sea. The route followed by the Suez Canal was surveyed by the French during Napoleon's invasion of Egypt (1798–1801). However, the survey actually discouraged plans for the canal because it overestimated the difference in sea level between the Red Sea and the Mediterranean, thereby making the canal appear to be a greater engineering challenge than it was. French interest in the region and the possibility of a canal remained,

➤ FERDINAND DE LESSEPS

Ferdinand de Lesseps was born in 1805 to a privileged French family. He was well educated, briefly studying law, but had no training in engineering. His early career was as a diplomat, and it was as a French diplomat quarantined in Alexandria in 1832 that he first read a memorandum, written for Napoleon, that discussed linking the Red Sea with the Mediterranean by canal. When Lesseps's diplomatic career ended (due to the volatility of French politics), he began work on creating the Suez Canal.

After spending decades building the Suez Canal, Lesseps sought another grand scheme and found it in a proposal for a canal across the Panamanian isthmus. Lesseps died in 1894 after the failure of his Panama Canal Company had severely damaged his reputation and that of his eldest son. After his death his widow and dependent children (he had married a second time late in life, and his last child was born in 1885) were given financial support by Suez Canal shareholders, as Lesseps had not become wealthy from his canal ventures.

—*Claire Brennan*

sultan in 1866. Even before that confirmation Lesseps had founded La Compagnie Universelle du Canal Maritime de Suez (Universal Company of the Maritime Suez Canal) in 1858 to build the canal. This was a private company that would build the canal, operate it, and then transfer ownership to the government of Egypt after 99 years. The proposed route made use of natural lakes in the region rather than pursuing the shortest possible course between the seas. While the lakes required deepening and stabilizing, their utilization reduced the work necessary to produce the canal.

Work on the canal began in 1859. It did not present insurmountable technical difficulties, but progress on the canal was slowed by political wrangling between Britain and France and between the Ottoman government and Egypt. Britain had reservations about building the canal because it would be under the control of a French company. The rulers of the Ottoman empire were constrained by British interests and by concerns that a successful and profitable canal would encourage Egyptian independence. These tensions made it difficult for the canal company to obtain Ottoman permission for the work to continue, raise funds in Europe, and obtain the necessary local labor. All this resulted in significant construction delays.

Working in a desert also presented some difficulties. It was necessary to dig another canal running eastward from the Nile near Cairo to the south end of the Suez Canal. Complete by 1862, this canal, known as the Sweetwater Canal, was dug parallel to the course of the Suez Canal, ran for half the length of the Suez Canal itself, and was navigable by small boats. It provided water to the workers, a means of moving materials to the work site, and a means of irrigating previously arid land, creating new wealth in the desert even before the completion of the ship canal. The canal also required the construction of a seaport. The first work undertaken on the canal was at the site of the future Port Said. As the port was built on shifting sand, 530,000 cubic feet of stone was brought from 150 miles west to build two stone jetties to stabilize the coastline; later 327,000 cubic yards of locally made concrete was used to stabilize the harbor floor.

as indicated by the 1833–1835 visit by the social reformer Prosper Enfantin and other members of the Saint-Simonian movement who sought to promote French science and industry. Enfantin and his followers investigated the possibility of building a canal and commissioned further engineering studies that indicated that the sea-level difference might not be as great as had been predicted. However, they failed to interest the Egyptian ruler, Muhammad Ali. When a plague epidemic struck Cairo they returned to France, where they continued to seek support for the construction of the canal.

The construction of the Suez Canal was finally undertaken by the Frenchman Ferdinand de Lesseps, a childhood friend of the Egyptian viceroy Said Pasha. Using new engineering studies, Lesseps was able to convince the viceroy of the viability of constructing the canal. In 1854 Said granted Lesseps the concession necessary to dig a canal across Egypt, and the concession was confirmed by the decree of the Ottoman

Until 1864 work on the canal was carried out by conscripted Egyptian labor, with up to 20,000 men, mostly peasants, each working for a month at the canal. Under diplomatic pressure from Great Britain, the use of conscripted labor was abandoned, and large steam-driven machines for dredging and digging were introduced. In addition, the French engineer overseeing the work, Alexandre Lavalley, invented two types of chutes to deposit dredgings directly on shore, doing away with the need for barges. The dredging machines were expensive, requiring £20,000 worth of coal per month, but between 1865 and 1869, 78.5 million cubic yards of material was dug from the course of the canal. Before the steam-driven machinery was introduced, between 1861 and 1864 only 20 million cubic yards had been dug by the Egyptian workers. The finished canal was 101 miles long, 32 feet in depth, and a minimum of 144 feet wide. Ships up to a maximum of 5,000 tons could use the canal.

The French empress Eugénie officially opened the canal in 1869 as part of a celebration that cost £1.3 million. Despite British obstruction during the building of the canal, once it was open it became an important route to India. As a result, in 1875 the British government seized the opportunity to buy canal shares held by the financially strapped Egyptian ruler and thus become co-owner of the waterway. The canal was very successful as a shipping route. As steam continued to replace sail, the canal could be used despite the difficult winds of the Red Sea. Although in 1870 only 486 ships, totaling less than 500,000 tons, used the canal, by 1882 the canal was operating at capacity. In 1908, 3,795 ships, with a total weight of more than 19.11 million tons, used the canal to shorten the voyage between Europe and Asia. The popularity of the canal led to the use of electric headlights from 1887 to allow ships to use the canal at night and to the widening of the canal to allow increased traffic.

Canal Building—Panama Canal

One of the two most important artificial waterways in the world, the Panama Canal cuts across the isthmus between North and South America in a series of locks and lakes extending 51 miles, allowing ships to pass between the Atlantic and Pacific Oceans and thereby shortening the voyage by approximately 8,000 nautical miles. Founded in 1879 by Ferdinand de Lesseps, the French *Compagnie Universelle du Canal Interocéanique* commenced excavation of the proposed sea-level channel only to encounter financial, technological, and medical difficulties during construction. On the verge of bankruptcy, owners of the French company offered their shares to the United States in exchange for \$40 million. Negotiations with the Colombians over the long-term rights to the project ended in their rejection of the U.S. offer of \$10 million and an annual payment of \$250,000 in rent, as agreed to in the proposed Hay-Herran Treaty.

President Theodore Roosevelt, anxious to secure U.S. control over the project, supported a Panamanian-led revolution, recognized the fledgling country, and authorized his secretary of state, John Hay, to negotiate the Hay-Bunau-Varilla Treaty, which granted the United States the sole right to control and operate the Canal Zone. Social and political unrest resulted in U.S. intervention in 1908, 1912, 1918, and 1925. In 1936, the United States relinquished the right of intervention by ratifying the Hull-Alfaro Treaty. During World War II, Panama granted U.S. requests for additional defense sites to protect the canal, many of which reverted back to Panama immediately after the conflict but some of which the United States continued to control for decades.

By the 1980s, a disputed election resulted in the imposition of sanctions and the withholding of the annual payment to Panama by President

Ronald Reagan. Continued tensions led to the loss of U.S. life, with a quick retaliation that ended with the capture and extradition of Panama's leader, Manuel Noriega, to Florida, where he was tried and sentenced to prison on drug-trafficking charges. By a treaty signed in 1977, Panama gradually assumed control over the Canal Zone, with the United States relinquishing all control by December 31, 1999.

Human Flight—From Hot Air Balloons to Kitty Hawk

Humanity has long had a fascination with flight, although the quest for flight involved far more than a contest to see who could build the first airplane. By the Middle Ages, humans had a firm grasp on various technologies that involved flight or manipulating air: sails, kites, helicopter-like toys, and primitive rockets, among others. Concepts for lighter-than-air balloons were developed in the seventeenth century, and balloons themselves appeared in the eighteenth century. During the late eighteenth and early nineteenth centuries, applications for balloons in both war and science appeared in the development of steerable airships. British, German, and French glider experiments in the 1890s provided a foundation for the Wright brothers' triumph in 1903, the first successful controlled, powered, heavier-than-air human flight.

In the second century CE the Chinese discovered that an evacuated eggshell would rise into the air if heated, and they later created miniature globe lanterns made of paper that flew like hot air balloons. The first person to actually fly a test balloon, however, was a young Brazilian-born priest named Bartolomeu de Gusmão, whose flight took place in 1709. The first successful manned balloon flight, which used a hot air balloon designed by the Montgolfier brothers, did

not take place until November 21, 1783. Their balloon reached an altitude of about 500 feet above Paris and managed to cover 5.5 miles in 25 minutes. A balloon invented by Jacques Charles that used hydrogen for buoyancy was flown shortly thereafter on December 1, 1793. Balloons using hydrogen or other lighter-than-air gases had greater lift and could be flown longer than balloons using heated air and soon came to dominate ballooning.

Recognizing the limitations of nonsteerable balloons, many inventors began trying to develop a steerable flying machine. The first engine-powered and controlled balloon, which came to be called a dirigible, was flown by Henri Giffard on September 24, 1852. Giffard flew almost 17 miles from Paris to Trappes, France, and proved that a lighter-than-air aircraft could be steered and controlled. Giffard's craft inspired a Golden Age of Airships, with many types of airships being invented over the next 50 years. An extremely successful type of rigid airship was pioneered by Count von Zeppelin in 1900. The term "zeppelin" eventually came to be applied to all types of rigid airships.

Balloons came to be used for a variety of civilian and military purposes. The first use of a balloon for military purposes was a Montgolfier brothers-designed aerostat (a balloon tethered to the ground) used for aerial reconnaissance by the French at the Battle of Fleurus in 1794. During the late nineteenth century balloons also were used for military purposes in the U.S. Civil War as well as in several British campaigns in Africa.

While successful lighter-than-air flying machines had been tested since the 1790s, it was not until the Wright brothers' efforts that a heavier-than-air flying machine flew successfully. On December 17, 1903, Orville and Wilbur Wright successfully tested their design for a controlled, powered, heavier-than-air aircraft. Over the next two years the brothers refined their invention into the first practical fixed-wing aircraft. The Wrights were able to achieve their breakthrough because of their invention of three axis-control, which allowed an aircraft pilot to steer effectively and maintain equilibrium. This technique has since become a standard feature of modern fixed-wing aircraft.

► DECEMBER 17, 1903, AT KITTY HAWK, NORTH CAROLINA

After several weeks of delays at Kitty Hawk caused by mechanical problems, the Wright brothers finally took to the air on December 17, 1903, making two flights each into a freezing headwind. The first flight of the day, by Orville, lasted only 12 seconds and covered 120 feet. The fourth and final flight of the day, by Wilbur, was the most successful; it covered 852 feet and lasted 59 seconds, achieving a top speed of just under 10 miles per hour at an altitude of about 10 feet. Unfortunately, this turned out to be the last flight for the first successful flying machine; after Wilbur landed, a strong gust of wind rolled the aircraft over and over along the ground, badly damaging it. It was never flown again.

—Andrew Byers

The Wright Brothers' first flight in the Kill Devil Hills near Kitty Hawk, North Carolina on December 17, 1903. Orville Wright is at the controls, while Wilbur stands to the right. (Library of Congress)

The Wrights did not design their first flying machine in isolation. On the contrary, they were aware of the many successful and unsuccessful efforts of other early aviation pioneers in Europe and America. Sir George Cayley, considered the father of modern aviation, produced dozens of glider designs, some as early as 1804, and made the first scientific studies of aerodynamics. Jean-Marie Le Bris made the first powered flight in 1856 in a glider pulled against the wind by a horse. John J. Montgomery later made the first controlled flight in a glider in 1883, as did a number of other aviators around the same time. Clément Ader also designed and built several self-powered but uncontrolled aircraft in the 1890s. The Wright brothers' aircraft was the first well-documented sustained flight in what is now considered an airplane rather than a glider or animal-assisted flying

machine. The Wrights were gifted engineers, although they lacked formal training, and integrated various technologies into their successful design to create the world's first airplane capable of powered, sustained, and controlled flight.

■ Introduction: Technology and Weapons

That the period from 1750 to 1914 saw numerous technological innovations in the design and manufacture of weapons is an understatement. At the onset of World War I in 1914, soldiers were equipped with rifles accu-

rate up to 2.5 miles, 20 times the range of muskets used in the Napoleonic Wars; some soldiers also were trained to use machine guns, capable of firing 400 to 600 small-caliber rounds per minute, numbers that were doubled by war's

end. Artillery crews had weapons that had undergone similar advances, especially after the introduction of recoil mechanisms and lyddite (picric acid) and TNT (trinitrotoluene) as ammunition in the 1890s and early 1900s. The maximum range of cannons and howitzers in the Napoleonic wars was less than 3,280 feet. Siege guns in World War I could fire almost 8 miles, and the freakishly large German Paris Gun, used at the end of the war, could fire a 210-pound shell 25 miles in the air with a range of 80 miles. By the early 1900s, a brigade of 3,000 soldiers could fire more artillery and rifle rounds in a single minute than the entire British army of 60,000 in the daylong Battle of Waterloo in 1815.

Advances in the design and manufacture of firearms, bullets, shells, gunpowder, and artillery played an important part in the history of nineteenth-century warfare, but other technological advances played equally significant roles. Many of the new weapons would have been impractical without the increased availability of cheap steel following the development in the 1850s of the Bessemer process, which allowed for the mass production of steel from molten pig iron. Steel was a key component of the new artillery pieces that began to pour from the factories of European armament makers from the 1870s onward. Steel also was used for armor plating on naval vessels and in the manufacture of armor-penetrating steel-cored bullets.

Advances in food preservation and preparation also had military ramifications. When techniques to produce canned meat, powdered milk, evaporated milk, and margarine were developed in midcentury, such products were quickly adopted by navies and armies. They improved the overall health of soldiers and sailors and made it possible for them to campaign or sail for longer periods without exhausting their provisions. Command and control capability was revolutionized by developments in communications. Until the 1790s all orders and reports were sent by ship or mounted messengers, methods that were both slow and unreliable. The first semaphore system, installed between Lille and Paris (a distance of approximately 120 miles) on orders of the French Legislative Assembly in 1792, consisted of a series of towers 5–10 miles apart

on which attached arms could be manipulated to represent 196 different symbols. Napoleon became an avid supporter of semaphore “telegraphy,” and on his orders semaphore systems were installed between France and cities in Germany, Italy, and the Netherlands to help him rule his empire, receive intelligence, and send orders. The semaphore system lost ground at midcentury to the electric telegraph, which was superior in terms of range and speed. The semaphore was first used in the Crimean War (1853–1856), enabling the French ruler Napoleon III to send orders and advice to his commanders 1,500 miles away. The next advance was the development of the wireless radio. After Guglielmo Marconi transmitted a radio signal across the Atlantic in 1901, the British Royal Navy became his best customer.

Perhaps the greatest changes in military planning and tactics resulted from the use of steam engines for land and sea transportation. European navies in the early nineteenth century, despite changes in ship design and armaments, basically were built according to designs first introduced in the 1500s. Beginning in the 1830s, however, ship design began to change when the first auxiliary steam engines were added to sailing ships. The British *Nemesis*, an iron-hulled naval vessel propelled by sails and two steam engines, was built in Manchester in 1839 and had its baptism of fire in the Opium War in 1841. In January the *Nemesis* defeated a fleet of Chinese war junks in the Pearl River and later contributed to the capture of Guangzhou. In the 1880s sails were abandoned for coal-burning steam engines, and steel replaced iron in ship construction. The era ended with a competition among the major powers over which could build the most formidable battleship. In 1905 the British launched the *Dreadnought*, a gigantic heavily armed steel-armored battleship powered by the latest steam turbine engines. Its design was copied by Germany (1907), Russia and Japan (1909), France (1910), and other powers (by 1914).

Regarding land warfare, the Crimean War was the first nineteenth-century conflict in which railroads played a role. In the winter of 1855 an 8-mile railroad was built between the British-controlled Black Sea city of Balaklava and

the location of the British and allied troops besieging Sevastopol, a heavily fortified Russian naval base. Constructed in less than three weeks at cost by the British railroad construction firm owned by Samuel Morton Peto, the Grand Crimean Central Railway contributed to the fall of Sevastopol in September 1855.

Railroads played a much more important role in the American Civil War. In the war's opening battle, fought at Manassas/Bull Run outside of Washington, D.C., the South won the battle when reinforcements under the command of Brigadier General Joseph E. Johnston arrived by rail from the Shenandoah Valley in western Virginia. Throughout the war the South continued to rely on railroads to move troops from one area to another as needed. In 1862 after Congress passed the Railways and Telegraph Act, the North established the U.S. Military Railroad, which under the command of General Herman Haupt had the authority to take over and run railroads when military needs dictated. Troops were specially trained by both sides for the task of repairing railroad lines damaged in battle or by guerrillas, and during General William T. Sherman's march through Georgia in November–December 1864, troops were ordered to cause irreparable destruction to the region's railroads. Rails were heated red in giant fires of railroad ties and then twisted around trees to make them totally useless and irreparable. When General Ulysses S. Grant began the Richmond-Petersburg Campaign in the summer of 1864, he set up an enormous rail depot at City Point, a town overlooking the James and Appomattox rivers, from which he provisioned his army. Railroads thus played a key role in the events leading to the Southern surrender at Appomattox in April 1865.

In Europe, railroads played an increasingly important role in military thinking, especially for Prussia and, after 1870, the newly united Germany. General Helmuth von Moltke (1800–1891), who served as chief of the Prussian and later German general staff for 30 years, was an avid student of the military possibilities of railroads as early as the 1840s and used them to good effect in the three Prussian victories over Denmark, Austria, and France between 1864 and 1871. As chief of the German general staff,

he devised war plans in which railroads could be utilized to concentrate forces at the start of a war for one decisive battlefield victory or to move troops and supplies to key areas in case of a longer defensive war. With the German rail system under state control, the army had veto power over the construction and modification of lines and required that railroad cars be designed so they could easily be converted to troop or weapons carriers. Railroads played a key role in the complex war plans drawn up by the general staffs of the major European states from the 1890s onward, and according to some historians of World War I, the generals pushed for war in the summer of 1914 before all diplomatic possibilities were exhausted mainly because they feared that any delay would ruin their elaborate plans for mobilization and deployment.

Von Moltke once told Kaiser Wilhelm I, "Build no more fortresses, build railways." Von Moltke also is quoted as saying that "No battle plan survives first contact with the enemy." This was borne out in World War I, in which the fighting on the Western Front turned into a war of attrition, with the two sides dug in behind trenches that stretched from the North Sea to Switzerland. With railway and telegraph lines destroyed by artillery, homing pigeons and trained dogs were employed to carry messages, and millions of horses and mules were used to carry supplies and weapons to the front. Some horses and dogs were fitted with gas masks, and many thousands were treated in veterinary hospitals. Nonetheless, as many as 2 million horses may have died.

—James H. Overfield

Semaphore System (Télégraphique) during the French Revolution

As Revolutionary France struggled against foreign threats, the French government was anxious to establish an efficient nationwide system of communication for political and military purposes. Among various proposals was that of Claude Chappé (1763–1805) who, together with his brothers Abraham, Ignace, and Pierre, spent several years experimenting with aural,

EXPANSION OF SEMAPHORE SYSTEM DURING THE FRENCH REVOLUTION AND THE FIRST EMPIRE

Date of Construction	Connecting Cities	Distance in Miles	Distance in Kilometers	Duration
1794	Paris to Lille	118	190	1794–1847
1794	Paris to Landau/Strasbourg	80	128	1798–1852
1798	Lille to Dunkerque	40	64	1798–1801
1798	Paris to Brest	130	210	1798–1853
1799	Strasbourg to Huningue	60	96	1799–1800
1803	Lille to Brussels	60	96	1803–1814
1803	Lille to Boulogne	50	80	1803–1816
1804	Paris to Lyon (via Dijon)	230	370	1804–1852
1804	Lyon to Turin	155	250	1807–1814
1804	Turin to Milan	62	100	1809–1814
1805	Lyon to Toulon	190	305	1805–1821
1809	Brussels to Antwerp	25	40	1809–1813

1813	Metz to Mainz	140	225	1813–1814

—Alexander Mikaberidze

mechanical, and electric telegraphs. Ultimately they settled on a semaphore system that involved a series of signal towers within binocular range of each other. The resulting network was a forerunner of the electrical telegraph systems that emerged several decades later.

After experimenting with a synchronized system that relied on both sound and visual cues, the Chappé brothers settled on a purely optical method that promised greater speed and clarity. On March 2, 1791, they built two telegraphs (in fact, two synchronized pendulum clocks that communicated through the sound of a bell) about 10 miles apart between the towns of Brûlon and Parcé and successfully communicated their first message: “If you succeed you will soon bask in glory.”

Not satisfied with their first prototype, Claude Chappé experimented with different designs, including a rectangular wooden frame with five sliding panels that could be displayed or obscured individually with pulleys to create coded sequences. By 1793, he suggested

constructing a series of telegraph stations, each consisting of a mast 16.4 feet and carrying a 14.7-foot movable cross-beam (regulator) with two 6.5-foot arms (indicators) fixed at each end. Indicators could be formed in different positions at intervals of 45 degrees, while the regulator itself had four orientations. In practice, these could be manipulated in various ways to signal alphabetic, numeric, or other coded signals between stations. On July 12, 1793, the semaphore system passed its first official test, and on July 26 the government decided to establish a state telegraph line and authorized construction of the first line between Paris and Lille. It was officially opened on July 16, 1794, and in August it was used to successfully report news of French victories within hours after they took place, which ensured the government’s continued support of the telegraph system.

However, the system was not without its problems. The time to transmit messages was longer than expected, and poor visibility and bad weather often caused transmission errors

and service interruptions. To address these issues, Chappé constructed auxiliary stations at shorter distances that could operate in low visibility. The size of the regulator cross-beam was increased to 49.2 feet to improve its visibility. Lanterns were used to allow transmission at night and in light fog. The mathematician Gaspard Monge (1746–1818) was consulted and suggested increasing the number of indicators from two to seven to increase code space and speed of transmission; this design, however, was hardly ever used.

Instead, Chappé developed a new coding scheme that allowed the telegraph system to transmit one character in about 30 seconds depending on conditions. The semaphore messages were encrypted, and a telegrapher in the receiving tower would simply read the signals through a telescope and retransmit them to the following tower. The telegrapher in the previous tower would check to see that the following tower copied his signals exactly. If not, he would signal an error. The process was repeated until the message was delivered to its final destination. Due to the encrypted nature of transmission, the operators were not privy to transmitted information, and only the directors of the system and inspectors could interpret the code. Each signal had to be recorded as a pictogram in a logbook as soon as it was received. Operators in each signaling tower, however, knew the limited set of control codes used to indicate errors, corrections, and so on.

By 1800, the telegraph network was at its early stages. After coming to power, Napoleon Bonaparte showed particular interest in developing the communication network and ordered the construction of four main branches extending from Paris and connecting the capital to major cities. With each station within telescopic sight of the next, the telegraph network included numerous stations, with over 50 between Paris and Strasbourg alone. By the mid-nineteenth century, some 500 semaphore stations, spanning about 3,106 miles, had been installed throughout France. The French system also inspired the British Admiralty, led by Lord George Murray (1761–1803), to develop a visual telegraph system using holes closed manually by movable wooden shutters. About 15 stations

were constructed between London, Deal, and Portsmouth. Several decades later, the British would become leaders in the electric telegraph industry.

The Development of the Submarine

Man has dreamed of traveling under the sea since at least the Classical Era. Various inventors produced different designs in the seventeenth and eighteenth centuries, but all were vexed by the problems of submerged propulsion and methods of attacking enemy ships. These problems continued into a more intensive phase of experimentation during the American Civil War and were finally overcome by the turn of the twentieth century. Submarines were rapidly incorporated into the world's navies after 1900.

In 1624 Cornelius Drebbel astounded the court of James I with a submersible boat operating in the River Thames. In the 1680s Frenchman Denis Papin built a submersible boat for the Landgrave of Hesse-Cassel, but seeing as Hesse-Cassel was landlocked, there was no immediate application for the vessel. Submarine warfare had its advent on September 6, 1776, when Sergeant Ezra Lee piloted a one-man submersible called the *Turtle*, designed by David Bushnell, to attack HMS *Eagle* in New York Harbor. Bushnell's design incorporated several features similar to Papin's. The *Turtle* was moved by a hand-cranked screw propeller and was armed with a gunpowder mine. Although Lee managed to maneuver the *Turtle* to his target, he failed to attach the mine to the hull.

Problems of propulsion and armament continued into the nineteenth century. In an effort

WILHELM BAUER'S EARLY SUBMARINES

Bavarian submarine pioneer Wilhelm Bauer built his first boat, *Der Brandtaucher*, in 1850. He became the first submariner to discover crush depth (at which pressure will collapse the hull), doing so the hard way during trials off Kiel on February 1, 1851. Fortunately, he and his two crewmen managed to escape the stricken vessel after allowing the internal and external pressures to equalize, earning another first: the first successful escape from a disabled submarine. Bauer's sources of German finance dried up, so he moved east to build a new submarine for the Grand Duke Constantine of Russia, *Le Diable-Marin* (or *Seeteufel*), in 1855. Capable of diving to 100 feet (30 meters), it provided yet another first: an underwater concert on September 5, 1856, as chamber musicians played to celebrate the accession of Alexander II.

—Melvin Smith

to break the Union blockade, the Confederate Navy commissioned a number of “Davids,” steam-powered semisubmersibles armed with spar torpedoes (an explosive charge at the end of a boom) with limited success. Their fate was often the same as that of CSS *Hunley*, a true submersible powered by a hand-cranked propeller and sporting a spar torpedo. On February 17, 1864, the *Hunley* sank USS *Housatonic* off Charleston but was lost with all eight hands in the process. The wreck of the submarine was raised in the summer of 2000, causing new debate as to the exact sequence of events that led to its loss.

A series of technological innovations in the late nineteenth century overcame the perennial problems of submarine navigation. Working for the Austrian Navy, British inventor Richard Whitehead developed a self-propelled torpedo in 1866. Spanish pioneer Isaac Paral used batteries and an electric motor to propel his experimental submarine in the 1880s. Also making its advent in the 1880s was the practical internal combustion engine, offering an alternative to steam engines.

These elements came together in the designs of Irish American inventor John P. Holland. He progressed from his first pedal-powered 1877

model through a series of improvements that incorporated the emerging technologies to produce the *Holland VI* in 1897. Commissioned into the U.S. Navy in 1900 as USS *Holland*, it was 54 feet long, was powered by a 50-horsepower gasoline engine while surfaced and by batteries while submerged, and was armed with a single torpedo tube. It served as the test bed for further submarine design for the next decade.

Holland's success at securing a naval contract sparked a bitter rivalry with a competing submarine developer, Simon Lake of Bridgeport, Connecticut. Lake began building submarines in 1894, wheeled designs that were more crablike than fishlike and were intended for civilian salvage and shellfish harvesting operations. Holland's contract inspired him to build his own submersible torpedo boat, the *Protector*, launched in November 1902. Unable to interest the U.S. Navy, Lake ultimately sold the submarine to Russia in 1904. Lake went on to a long and distinguished career as a submarine designer and innovator, building submarines for European buyers and several commissioned by the U.S. Navy.

France commissioned its first submarine, the diesel-electric *Aigrette*, in 1900. Britain followed suit in 1901, launching a submarine built under Holland license by Vickers. Germany borrowed ideas from both Holland and Lake to launch its first Krupp-built submarine in 1906. The Germans saw the submarine as a way to neutralize British naval superiority, a view that had grave consequences during the First World War.

European Navies in an Age of Steam and Steel

European navies transitioned gradually from wood and wind to steam and steel during the nineteenth century. Early steam engines and

propulsion methods were not ideally suited to warship design, nor were iron and steel eagerly accepted as alternatives to wood for military hull construction before the mid-nineteenth century, retarding the adoption of these new technologies. Advances in gun design and improvements in machinery gradually swayed naval opinion, ushering in a period of rapid ship-design evolution culminating with the launching of HMS *Dreadnought* in 1906. Doctrine had to evolve with technology as nations decided the most economical use of the expensive new units.

Advances in naval gun design took place between 1815 and 1853. Two key innovations were introduced: (1) guns capable of firing explosive shells that greatly increased the damage inflicted on the target vessel and (2) rifled barrels that increased the likelihood of actually hitting the target vessel. These innovations spelled the demise of the wooden-hulled warship. At the same time, steam made its advent at sea.

First-generation maritime steam engines were neither powerful nor fuel-efficient, limiting the operational range and speed of a warship. They were also lacking in reliability, thus forcing the design of hybrid steam and sail vessels. These engines were coupled to side paddlewheels that took up a significant amount of space on either side of the ship's hull, limiting the space available for the broadside battery of guns. More reliable, powerful, and efficient engines evolved as the century progressed, and these engines, when coupled with the development of the screw propeller in the 1840s, eliminated these basic problems. Vulnerable propulsion systems could be placed below the waterline, farther out of harm's way, and no longer took up valuable armaments space.

European navies experimented with iron plate armor with varying degrees of success in the 1830s and 1840s but did not adopt any designs until the construction of armored floating batteries for the close-inshore work of shelling Russian fortifications during the Crimean War. From the success of these experimental expedients, France commissioned the iron-clad FS *La Gloire* in 1859, and Britain commissioned the iron-hulled HMS *Warrior* in 1860. However, neither ship ever fired a shot in combat. The actual test of the iron-clad steamship in battle took place with the 1862

THE LOGISTICS OF EMPIRE

The latter half of the nineteenth century saw an explosion of imperial expansion for a variety of reasons, religious, political, and economic. One of these motivating factors was linked intimately with the development of a steam and steel navy. In the days of sail ships, naval squadrons and individual ships could and did operate for months at a time far from home ports, their endurance limited only by the needs of water and victuals. Repairs required only wood and hand tools for the most part and could be accomplished in even the most primitive of settings. Steel hulls and steam engines, however, required substantial machine shops for maintenance and vast stores of coal for fuel. Any nation wishing to project power on a global basis had to establish naval repair and coaling stations on a global basis as well. As a result, previously discounted bays and tiny islands suddenly became eagerly sought imperial properties.

—Melvin Smith

confrontation between USS *Monitor* and CSS *Virginia* at Hampton Roads. Although the battle was inconclusive, with neither ship able to sink the other, it did demonstrate the potential of armored ships and provided justification for the advocates of steam and steel. Warship design underwent a radical shift during the subsequent decades of the nineteenth century with the development of even larger guns, better armor, and more powerful engines. Building large and heavily armored battleships was expensive, but new and cheaper technologies such as the torpedo and underwater mine were pioneered. These cheaper alternatives led to differing schools of thought as to fleet design and purpose.

In France Admiral Theophile Aube developed the *Jeune École* (Young School), the idea of which was that France could not hope to out-build their traditional British rival. The *Jeune École* argued that instead of trying to build capital ships and seek a fleet engagement, the French navy should concentrate on fast torpedo boats to negate enemy battleships and other light units to carry out a *guerre de course* against enemy commercial shipping.

Across the Atlantic, American naval theorist and historian Alfred Thayer Mahan introduced his concept of command of the sea in his seminal book *The Influence of Sea Power upon History* (1890). Mahan argued that the greatest nations in history had become such by establishing command of the sea. This command was gained by creating a fleet capable of destroying that of the enemy, thus giving friendly merchant shipping freedom of movement while denying that freedom to the enemy. His views were eagerly accepted in Britain and Germany and contributed to their naval arms buildup around the turn of the twentieth century.

A third school of thought emerged with the publication of *Some Principles of Maritime Strategy* by Sir Julian S. Corbett in 1911. A lecturer at the British Royal Naval College, Corbett pointed out that it was almost impossible for a war to be decided by naval operations alone. While it could be beneficial to pursue a *guerre de course* and certainly prudent to maintain a strong fleet, a proper maritime strategy was one subordinated to the needs and realities of land warfare. This view, although controversial among his contemporaries, actually came closest to describing the way that navies were actually used in the decades before 1914.

Firearms

Handheld man-portable weapons date from the discovery of gunpowder, the first propellant known to man. Gunpowder is a coarse mixture of saltpeter, charcoal, and sulfur. The earliest firearms were muzzle-loaded. The barrel of the weapon was a simple smooth tube, with a small aperture near the closed end to allow the firing spark access to the gunpowder charge. Firearms were not common until about 1375. The earliest firing method was by means of the matchlock:

simply a length of fuse held in a clamp that could be moved into the firing position by the musketeer when he chose. Naturally, such a firing method required the musketeer to keep his fuse alight, not an easy task in rain or wind. The next developed firing mechanism was the wheel lock, followed by the snaphaunce, the flintlock, and the miquelet. All worked on the principle of causing sparks to be generated by a flint that lit a powder train, the train in turn firing the main charge. In terms of time, from the development of the wheellock to the development of the next stage of ignition—the percussion system—a period of 300 years elapsed.

Firearms were inevitably rough weapons until the middle of the nineteenth century simply because every maker had his own standards and methods of measurement. This meant that calibers were erratic, even when makers were in the same town or even on the same street. Furthermore, bullet makers were equally nonstandardized, so it was lucky that the main projectile was the lead ball, which could be adjusted reasonably easily in the field.

During the nineteenth century, there was a complete change in the technical aspects of firearms. The Reverend Dr. Alexander Forsyth (1749–1818) patented the percussion system in 1807. This system still operated in a muzzle loader, but the ignition charge was sealed in a percussion cap that the firer placed over a nipple, which was connected to the main charge. When the trigger is pressed a hammer hits the cap, causing a high-pressure explosion that ignites the propellant.

Pistols developed in exactly the same way as muskets, and the calibers of all weapons up to the mid-nineteenth century was large in comparison with today's firearms. This was due to problems in barrel making, for no effective method had been found to make barrel steel capable of withstanding the propellant explosion except by thickness of the barrel; furthermore, gunpowder was so weak in its explosive effect that large amounts were needed to propel the ball down the barrel and on to the target. This insoluble circle was broken with the invention of nitrocellulose powders in the nineteenth century, together with the development of standards and gauges by the Englishman Joseph Whitworth

(1803–1887) and the invention of the cartridge and rifling.

The rate of fire of standard military firearms did not increase fundamentally until the same time. In 1812 Dean Pauly invented the first cartridge-loaded breech-loading rifle, and then Emile Lefauchaux invented the pin-fire cartridge. At last the igniter, the propellant, and the bullet were combined into one unit. This was of fundamental significance to Samuel Colt (1814–1862) when he invented the first repeating firearm, which enjoys great status today as the first true modern firearm.

By the second half of the nineteenth century, firearms were beginning to operate in the same way as they do today. The breech-loaded weapons were firing a unitary cartridge, and the barrels were rifled, enabling sights to become things of accuracy rather than indicators of the possible final resting place of the projectile.

The next development was even more significant: single-shot rifles were standard issue until the bolt action was invented. Single-shot weapons were loaded by means of rolling blocks, falling blocks, or lever or breaking action. This meant that only a slow rate of fire was possible, although this was a much higher rate than that ever achievable by the muzzle loader. The bolt action, however, allowed the rifleman to reload his weapon by means of a mechanical device that would eject the spent cartridge from his last shot and load a fresh cartridge into the chamber from the magazine. Military rifles were now capable of firing from 5 to 15 aimed rounds per minute. Machine guns were the next logical step. One of the earliest firearms that has seen ubiquitous use is the pistol. The small, often concealed, hand weapon is for local protection only, but it has a long history. Its technical development has mirrored that of the rifle, and so flintlock pistols marched side by side with flintlock muskets. By the early part of the twentieth century there were automatic pistols, however, that were well in advance of rifle technology of the time.

One aspect of the firearm that leads the way in development is the cartridge. Since all-in-one cartridges were first invented, the caliber of the military round has diminished considerably. Snider-rifled muskets fired rounds of .577-inch

caliber, while the Martini rifle fired rounds of .45-inch caliber. World War I saw weapons of calibers around 8 millimeters, or about 0.3 inches.

Artillery in the Nineteenth Century

Artillery, the king of battle in the European military tradition, was first introduced into warfare in the 1300s and rose to prominence as a service arm during the 1600s. As a technology it underwent gradual minor improvements and innovations that did not radically alter the basic design for centuries before the mid-1800s. Advances in materials and manufacturing produced a rapid evolution of artillery during the latter half of the nineteenth century. Armament manufacturers in Europe, such as British Vickers, German Krupp, and Austro-Hungarian Skoda, developed numerous innovations to artillery pieces that increased their potential for use on the battlefield in terms of shell sizes, accuracy, and ease of use.

Preindustrial nineteenth-century artillery consisted of smoothbore muzzle-loaded guns charged with black powder, essentially a line-of-sight weapon with an effective range of 1,000–2,000 yards. Military organization generally divided artillery into two classes: garrison artillery, the large guns housed in fixed fortifications, and field artillery, the lighter weapons on

► THE GUNS OF AUGUST

The culmination of nineteenth-century innovation in artillery came with the start of World War I in August 1914. German plans for invading France called for an advance through Belgium by force if the request for free passage was refused. Belgium had built a series of heavy forts at Liège and Namur in the wake of the Franco-Prussian War and defied German demands. The Germans used massive Krupp 420-millimeter (mm) (nicknamed “Big Berthas”) and Skoda 305-mm (nicknamed “Slim Emmas”) artillery pieces to crack these forts one by one during the first ten days of the war. At Fort Loncin outside Liège a round from a Big Bertha penetrated the main magazine, causing a shattering detonation that destroyed the fort almost entirely and killed over half of the 550 defenders. That explosion announced that World War I would be a war dominated by the guns.

—Melvin Smith

mobile horse-drawn mounts that accompanied the army on campaign. The guns could fire a variety of projectiles, from solid shot for battering fortifications to grape shot (and later canister shot) for close-in antipersonnel work and exploding shells (later replaced by shrapnel shells) for more distant antipersonnel targets. The rate of fire was slow; a well-drilled gun crew could fire about two rounds per minute. Accuracy was more of an art than a science for a number of reasons. The cumbersome muzzle-loading drill aside, each time the weapon fired the recoil sent it rolling back several feet. Before it could be fired again it had to be rolled back up into position and resighted. Even if a master gunner laid the piece on target, a round ball fired from a smooth barrel wobbled in flight, making a direct hit a matter of luck rather than design.

The second Industrial Revolution provided a number of crucial innovations that led to a rapid evolution of artillery. Improvements in metallurgy moved the artillery tube from bronze or brass to iron and ultimately to steel construction capable of withstanding much larger propellant charges. The size of artillery pieces increased, with the weight that the gun carriage could bear being the only effective limit. The emerging chemical

industries provided high-explosive propellants and bursting charges, while advances in machine tooling provided methods of rifling cannon barrels and, along with the introduction of fixed ammunition, allowed the development of effective breech-loading systems. As a result of these innovations, guns could fire a heavier shell more than twice as far and more accurately than ever before, plus the shells carried far more destructive force downrange. Breech loading increased the rate of fire, but the problem of recoil and the necessity of resighting the gun after each shot still limited the effective speed of the weapons to about six rounds per minute.

Recoil was not tamed until the very end of the century with the introduction of the French M1897 75-millimeter field gun in 1897. The French 75, as it came to be known, used an oil-air compression system that absorbed the recoil energy of firing and then recycled that energy to return the barrel to firing position, all without moving the carriage. Since the carriage did not move, only minute adjustments were needed between rounds to keep the gun on target. With a good crew, it was capable of 20 to 30 rounds per minute. Once the effectiveness of this weapon was demonstrated during the suppression of the Boxer Rebellion in 1901, other nations developed their own quick-firing guns in very short order.

The Machine Gun

The machine gun is a weapon that fires cartridges automatically as long as the trigger is pressed. Rapid-fire weapons had long eluded inventors until nineteenth-century technological developments made them possible. The modern machine gun was invented by Hiram Maxim in the 1880s and was quickly followed by a variety of weapons designed by other inventors. By 1914

the machine gun had been integrated into European militaries and was one of the reasons for the stalemate of the Western Front.

The greatest obstacle to early rapid-fire weapons was how to get bullet, propellant, and the ignition source to work automatically. Although weapons such as the 1718 Puckle Gun may have worked, they relied on multiple individually loaded barrels or chambers and flintlock ignition. Only after the development of the metallic cartridge that incorporated bullet, powder, and primer into a single unit during the mid-nineteenth century did rapid-fire weapons become a useful technology. The most famous of these early quick-fire weapons was that of Richard Gatling, who patented his gun in 1862.

The Gatling gun and its competitors, the Gardener and Nordenfelt guns, were multiple-barreled weapons that were operated by the gunner turning a crank or pulling a lever that loaded and fired each barrel in turn. As such, they mechanized the firing process without exactly being automatic weapons, making it a point of debate among historians as to whether or not they qualify as machine guns. Regardless of semantics, they were all large and cumbersome weapons and had a reputation for jamming at inopportune moments.

The fully automatic machine gun was patented in 1883 by Hiram Maxim, an American electrical inventor who was at the time residing in England. Maxim's design used the recoil energy of the cartridge as it fired to operate the bolt, ejecting the spent cartridge and loading a new round. Unlike earlier weapons that required continual operation of the crank, this process repeated automatically as long as the trigger was depressed until the weapon ran out of ammunition. Furthermore, the Maxim gun used a looped cloth belt of cartridges, whereas earlier weapons relied on gravity-fed magazines. Maxim also insisted on tighter manufacturing standards for ammunition, which reduced the problem of jamming. With a single barrel cooled by a water jacket, the Maxim gun was much less cumbersome than previous weapons but was still a heavy crew-served weapon.

Other designers followed the trail blazed by Maxim as the century drew to a close, developing different operating, cooling, and feed

The first fully automatic machine gun, developed by Hiram Maxim in 1883, weighed 60 pounds, with a length of 42.5 inches, and was capable of firing 550 rounds per minute. Maxim later introduced a second design in 1885 that was used unchanged by armies all over the world until World War II. (Art-Tech)

mechanisms. John Browning's first production design, the 1895 Colt Potato Digger, tapped off a portion of the expanding gasses behind the bullet to operate his mechanism; the Franco-American Benet-Mercie (called the Hotchkiss in British service) was likewise gas operated but used cartridges fitted in a metal strip instead of a belt feed. Both were air cooled and more portable than the Maxim but remained tied to tripod mounts. The first real man-portable machine gun was designed by American Isaac N. Lewis in 1911. Adopted by the British in 1915, the air-cooled gas-operated Lewis Gun was fed by a 47-round drum magazine and weighed 26 pounds.

Although European governments were quick to acquire the Maxim gun or produce their own indigenous equivalent, European

commanders were slow to integrate the weapon into their tactical doctrines. The defensive potential of the machine gun was underestimated, which contributed greatly to the development of the stalemate of the Western Front in the First World War.

Land Mines

A land mine is a self-contained explosive device placed on the ground or underground that explodes when tripped or stepped on by a soldier, animal, or vehicle. Land mines were known for most of their history as “infernal machines” or some other uncomplimentary term. Soldiers feared and despised them because their victims had no chance to defend themselves or strike back. Land mines reached their technical maturity on the eve of World War I but did not see widespread use until World War II. In the twenty-first century, they provide a cheap and indiscriminate method for poorer countries and groups to strike their enemies.

Ancestors of modern land mines can be traced back at least 1,000 years. Chinese armies in the third century CE and Roman legions both sought to impede attackers by placing spikes in holes in the ground and covering them with a thin layer of dirt. During the European Middle Ages, armies made use of devices called caltrops, or crows’ feet, four-pronged spikes that were scattered aboveground. These early devices were intended not to kill but instead to slow down an assault and to force it into areas covered by missile-firing weapons.

With the invention of gunpowder, the land mine became a weapon designed to kill. By 1530 CE, the first explosive mines appeared. Known as *fougasses*, they consisted of chambers dug into a fortress’s defenses. A charge was placed in the chamber, and rocks, broken glass, or pieces of metal were packed on top of it. When the charge was set off, the material flew upward or horizontally, depending on how the chamber was oriented. These first land mines had weaknesses, however. If the powder became damp, it would not fire; similarly, powder fuses, necessary to detonate the device, would not work in rainy or windy weather. As a defensive weapon, they continued to be used through the period of the Napoleonic Wars.

The self-contained mine known as the *flad-dermine* was invented by the German military engineer Samuel Zimmerman in the 1570s. Flad-dermines used flintlock mechanisms connected

➤ A UNION SOLDIER’S VIEWS OF LAND MINES

Calvin Mehaffey, from Lancaster, Pennsylvania, was a junior officer in the Union Army; his letters home are preserved in the University of Michigan’s Schoff Civil War Collections. After the Confederate retreat from Yorktown in 1862, he had this to say about the enemy’s use of land mines, which he referred to as “torpedoes”:

“Where they are designed to kill a Division or Regt in their charge upon fortifications it is proper [to leave torpedoes], but when an army retreats, thereby acknowledging that they are afraid to fight and hides a few shells to kill the individual who treads on them, it is down right murder for the killing

of one or a dozen of men in that manner does not in the least determine their victory or our defeat. If in so doing they could kill fifty thousand men it would be perfectly fair and not inconsistent with warfare, but to blow up a telegraph boy in the pursuit of his calling is both murderous & barbarous.”

—Timothy J. Watts

to surface trip wires to set off a charge of gunpowder packed into barrels, pots, or other waterproof containers. During the nineteenth century, these self-contained mines adopted the percussion fuses used in firearms to set off their charges. The mines were usually buried just below the surface and were set off by tripwires or by someone stepping on them. Unlike the fougasses, self-contained mines did not need to be set off by an observer. For the first time, land mines became indiscriminant killers.

The most widespread early use of land mines took place during the American Civil War. Confederate general Gabriel James Rains, who had worked since 1840 to develop a practical land mine, developed a reliable pressure-sensitive fuse. During the Union advance on Richmond in the spring of 1862, Rains planted his first mines while stationed at Yorktown. On May 4 a Union cavalryman was blown up by a mine, and his puzzled comrades found more mines buried nearby. Near Williamsburg, more soldiers were killed by Rains's mines. The army's advance was held up for three days while soldiers searched for more "infernal machines." Fear and loathing of the mines was general even though casualties were generally light. Defensive mines were used in other locations by the Confederacy and were effective in channeling attacking Union forces into certain areas and helping break up assaults. When Richmond finally fell in April 1865, Union troops found nearly 1,300 mines buried on the roads. Five of Rains's mines were found near Mobile in 1960 and were still in working condition.

Other armies adopted land mines during the late 1800s. British soldiers manufactured explosive devices for use against the Mahdi army in Sudan during the 1880s. They also used mines in South Africa during the South African (Boer) War to protect railroads and at river crossings. During the Russo-Japanese War, the Russians used land mines to protect Port Arthur. Some of their mines used pressure to complete electric circuits for ignition, a significant technological advance. In response, the Japanese organized volunteer suicide squads to throw themselves on the Russian mines.

In 1912 the Germans began to manufacture a pressure-sensitive mine. Only a small number were available when World War I broke out.

When combat on the Western Front turned into trench warfare, many of these mines were placed among the barbed-wire entanglements. German troops, usually on the defensive, also made many improvised devices. They buried artillery shells, with the fuses exposed, in no-man's land. These fuses were specially made and replaced the original ones. They could be set off by wires or small rods. Later, the Germans developed antitank mines to break the tracks of the Allied tanks. Nearly 3 million land mines had been produced by the end of the war in 1918.

Barbed Wire

Barbed wire was invented in the 1800s to prevent cattle from wandering the vast American plains. During World War I, however, it contributed to the deadlock on the Western Front, and tangles of wire came to symbolize the industrialized nature of the war and the inhumanity of its violence.

Humans in antiquity made wire to make jewelry and later made use of it for practical purposes such as the manufacture of pins and wool cards, brushlike devices for combing wool fleece. Demand for wire increased in the industrial era, especially after the invention of the telegraph. During the American Civil War, both sides used telegraph wire for military purposes. In addition to communications use, soldiers strung telegraph wire between trees, stumps, and rocks to trip up attackers and break up formations. The tactic was moderately successful but failed to have a major impact on military planning and strategy.

In 1874, a 60-year-old Illinois farmer, Joseph F. Glidden (1813-1906), patented the first successful

Soldiers during World War I contend with barbed wire. Barbed wire contributed to the deadlock on the Western Front. Tangles of wire came to symbolize the industrialized nature of the war and the inhumanity of its violence. (National Archives)

barbed wire. He recognized that the lack of trees on the American plains made it impossible to control livestock with traditional wooden fences. Glidden used a coffee grinder to make barbs that were placed at regular intervals on a wire. Another wire was then twisted with the original strand to keep the barbs from slipping. The result was a lightweight fencing material that could be used anywhere. The demand for barbed wire was coupled with the simultaneous development of cheaply produced steel. In 1901, the United States produced over 135,000 tons of barbed wire, and the open range was no more.

Military leaders soon recognized barbed wire's value in defensive positions. In 1888, British military manuals recommended its use. During the Spanish-American War, American troops used strands of barbed wire to defend their camps from surprise Spanish attacks. One of the most controversial uses of the fencing materials was during the South African (Boer) War. During that conflict, British forces used lines of blockhouses and barbed-wire fences to cut off Boer forces from their civilian supporters. Both black and white South Africans were herded into concentration camps and fenced in. In the Russo-Japanese War of 1904–1905, Russian forces defending Port Arthur used multiple lines of barbed-wire obstacles to blunt Japanese assaults.

The Russo-Japanese War was a rehearsal for World War I in many ways. By November 1914, warfare on the Western Front settled into a deadlock of trench lines from Switzerland to the English Channel. Specially produced military barbed wire, with larger barbs, was strung in thick belts by both sides to protect the trenches. When coupled with machine guns, the wire was an almost impenetrable obstacle. Special pickets to hold the wire consisted of two flat pieces of steel, formed into an “L” shape. Slots on the side held the wire in place. The pickets were either driven into the ground or had a screw attachment for silent emplacement. Attempts to cut the wire with artillery shells were usually unsuccessful. The flexible wire either sprang back to its original position or was blown into the air and landed in a more impenetrable mess than before. Too many times, infantry who attacked enemy trenches were stopped by wire with no gaps and cut down by machine guns.

Attacking infantry usually had to force their way through the wire on their own. Wire cutters were used to create gaps, but it was slow work and usually attracted enemy fire. Grappling hooks were sometimes used to drag the wire out of place, with limited success. Other methods included covering the wire with boards, blankets, or human bodies to allow soldiers to run across. Explosives, such as Bangalore torpedoes (explosive devices placed at the end of a long expandable tube), were sometimes used to blow holes in the wire. The need to overcome the combination of barbed wire and machine guns led directly to the invention of the tank by the Allies. Tanks were able to crush the wire or drag it out of the way of following infantrymen.

Barbed-wire obstacles became one of the most enduring images of trench warfare. Small parties of men slipped out of the trenches at night to put up or repair their own wire or to cut the enemy's. In the aftermath of attacks, dead or seriously wounded soldiers were often left on the wire. Their bodies, slowly decomposing, became one of the many horrors of the war.

The Armament Makers—Krupp, Skoda, and Schneider-Creusot

During the nineteenth century a variety of manufacturing sectors experienced the vast changes in production and organization collectively known as the Industrial Revolution. Military production was no exception, and as in a number of other industries, tremendous arms conglomerates formed. Although these massive companies—Vickers Limited, Schneider et Cie, Skoda

Werke, and the giant Krupp works—had their respective national identities, they marketed their wares aggressively on a global basis, often selling or licensing the production of weapons to enemy nations. In the wake of the First World War the makers of the weapons themselves came under fire as one of the principal reasons for both the outbreak of the war and the shocking casualty figures thereof.

All of these companies sprang from humble and completely nonmilitary origins. The Vickers Company in Britain serves as an excellent example. The company got its start in Sheffield as a steel foundry in 1828, diversified into producing marine shafts and propellers in the 1860s and 1870s, and only ventured into arms production with artillery in 1890. Following the acquisition of the Barrow Shipbuilding Company and its subsidiary, Maxim Nordenfeldt Guns and Ammunition Company, in 1897, the company became Vickers, Sons and Maxim, producing everything

➤ CONDEMNING THE “MERCHANTS OF DEATH”

In 1934 the U.S. Senate convened a special committee to investigate the role of munitions manufacturers in American entry into the First World War. Although the Nye Committee as it came to be known focused primarily on American firms, its findings in 1936 condemned the entire international arms manufacturing system.

The following is from the report of the Nye Committee:

“The committee finds, further, that the intense competition among European and American munitions companies with the attendant bribery of governmental officials tends to create a corrupt officialdom, and thereby weaken the remaining democracies of the world at their head.

The committee finds, further, that the constant availability of munitions companies with competitive bribes ready in outstretched hands does not create a situation where the officials involved can, in the nature of things, be as much interested in peace and measures to secure peace as they are in increased armaments.

The committee finds also that there is a very considerable threat to the peace and civic prog-

ress of other nations in the success of the munitions makers and of their agents in corrupting the officials of any one nation and thereby selling to that one nation an armament out of proportion to its previous armaments. Whether such extraordinary sales are procured through bribery or through other forms of salesmanship, the effect of such sales is to produce fear, hostility, and greater munitions orders on the part of neighboring countries, culminating in economic strain and collapse or war.”

The Nye Committee had enormous impact on public and lawmakers’ opinions, encouraging a steadfast sentiment of isolationism in the United States in the 1930s, as major companies moved away from arms production and only after fierce debates did the United States enter World War II.

—Melvin Smith

from rifle cartridges to warships. Further diversification came after the turn of the century, with Vickers Limited (as it became in 1911) producing machine guns, artillery, airships, submarines, and aircraft.

Krupp had similar beginnings, starting as a small Essen steel manufacturer in 1812 and not producing even a prototype weapon until 1847; until that point the company's bread and butter had been precision dies and castings. By the turn of the century Krupp produced heavy artillery and warships for the kaiser. Banker Joseph Eugene Schneider bought a defunct iron foundry in Creusot in 1833, but the firm's only indirect contribution to arms building was in the form of marine steam engines until 1870, when they began a line of artillery. Despite becoming the premier artillery producer of France, Schneider remained a major (if not the major) civil engineering firm of the nation. Skoda Werke in Austria likewise began as a small civilian metallurgical concern in the 1860s and remained a diversified producer of civilian goods after the introduction of a munitions line.

The reason for the fame of these companies was, however, the production of munitions and weapons of war. In the uncertain years surrounding the turn of the twentieth century, vast fortunes were accumulated by these companies. Armies grew larger, technological innovations rendered older weapons systems obsolete in rapid succession, and nations with little or no industrial base turned to established companies to provide new weapons. This bred cutthroat competition between the arms makers, who often resorted to playing on the fears of their customers, sabotaging the demonstrations of their rivals, and outright bribery of government officials. The tremendous fortunes generated by these sales gave the companies that commanded them significant political clout, particularly when the numbers of their employees and their diverse nonmilitary output are taken into account. Companies could and did argue that what was good for Krupp (or Vickers or Schneider or . . .) was good for Germany (or Britain or France or . . .), as they were significant drivers of their national economies.

As a very visible part of the old order, the munitions makers were the target of a lot of

popular discontent and disillusionment in the postwar political environment. The aggressive marketing techniques employed during the two decades before the start of the First World War were roundly condemned in the wake of the war but in fact reflect little more than the standard, if shady, business practices of the day.

Dreadnoughts

The British battleship HMS *Dreadnought*, launched in 1906, represented a revolutionary new design of battleship, featuring an armament of all heavy guns that transformed naval warfare. The *Dreadnought* was so advanced that it rendered all other battleships obsolete. Unfortunately the design was easily copied, and soon other countries, especially Germany, Britain's most serious naval rival, were building their own dreadnoughts. This initiated the naval race between Germany and Britain that preceded the First World War, during which both countries built increasingly powerful and expensive dreadnoughts.

The idea for the *Dreadnought* was pursued by Admiral Sir John Fisher, who became first sea lord of the British Admiralty in 1904. Fisher wanted to build high-speed battleships that would carry all heavy guns and minimal armor so that it could sink enemy cruisers and battleships alike. Opposition within the Royal Navy meant that he had to accept a design that carried more armor. The ship's top speed was lowered as a result.

Fisher insisted that construction of the *Dreadnought* be carried out as quickly as possible. The normal construction period for a battleship was three years, but the *Dreadnought* was built in much less time. The keel of the *Dreadnought* was laid down in Portsmouth on October 2, 1905. It was launched on February 9, 1906, and sailed for the first time on October

Deck of the HMS Dreadnought (Library of Congress)

3, 1906. The ship was completed by December 1906 at a cost of £1.7 million.

Previous battleships had carried 4 heavy-caliber guns with an assortment of medium- and smaller-caliber guns. The *Dreadnought* carried 10 12-inch guns in double turrets, of which eight could be fired on a broadside. The *Dreadnought* also carried 18 12-pound guns for defense against enemy torpedo boats and 5 18-inch torpedo tubes.

The *Dreadnought* was powered by steam turbine engines that gave a top speed of 21.5 knots on trial. The *Dreadnought* was therefore at least three knots faster than its competitors. The ship displaced 21,845 tons fully loaded and carried a crew of 773. It was 526 feet long with a beam of 82 feet. The *Dreadnought* carried 4 inches of armor on the deck, 11 inches on the turrets, and 4 to 11 inches on the ship's belt, meaning the armor on the side of the hull. The *Dreadnought* had superior firepower to any other comparable battleship with sufficient speed to ensure that its enemies could be caught.

Other countries such as the United States were soon constructing dreadnought designs, but Germany caused the British the greatest concern. The naval race, the building by Germany and Britain of increasingly complex and expensive dreadnoughts, reached a peak between

ARMAMENT OF THE HMS DREADNOUGHT

Unlike earlier battleships that carried a mix of different-caliber guns, HMS *Dreadnought*, completed in 1906, carried a main armament made up exclusively of heavy guns. As a completely new design of warship, the *Dreadnought* revolutionized naval warfare and rendered older types obsolete. Between 1906 and 1914 all leading naval powers frantically began construction of their own versions of dreadnoughts. The naval race between Britain and Germany contributed to tensions that led to war in 1914.

—Paul Doerr

1908 and 1910. Britain's greater number of dockyards and larger skilled workforce ensured that Britain entered the First World War with more dreadnoughts than Germany.

By 1914, however, the *Dreadnought* itself was obsolete and too slow to keep up with the main fleet. The *Dreadnought* never fired its guns at the enemy, although it did sink a German submarine, the U-29, by ramming on February 18, 1915, the only instance of a battleship sinking a submarine in naval history. The *Dreadnought* served most of the war as the flagship of the Third Battle Squadron but missed the Battle of Jutland in 1916. The ship was paid off, or retired, from the Royal Navy, in 1920 and broken up for scrap in 1922.

■ Introduction: Science and Scientific Activity, 1750–1820

Science shared in the revolutionary transformation of world society in the period 1750–1820. This transformation was both internal, as various branches of science expanded their content and methods, and external, as science occupied a more central place in culture. Scientific developments seemed more closely related than ever to obvious technological advances, contributing to the Enlightenment and the revolutionary ideal of progress.

An important development in science was the rise of state sponsorship of specific scientific projects and scientific institutions with narrowly defined utilitarian goals. The late eighteenth century saw a vastly increased coordination between science and state power, often mediated through institutions like Revolutionary France's First Class of the Institute and Britain's Royal Society. These efforts included the creation of the metric system and the spread of botanical gardens for agricultural research. Not only governments saw science as pragmatically useful. Scientists, particularly in Great Britain, also contributed to the expansion of private capitalist enterprise in the era of the Industrial Revolution, and capitalists, engineers, and scientists often worked closely together.

Western science became increasingly global along with Western empires. Science was an important part of imperial control and administration, and the period saw numerous scientific expeditions such as those of Captain James Cook in the South Pacific and Spain's Royal Botanical Expedition to Mexico. French scientists accompanied Napoleon's expedition to Egypt. The newly independent nations of the Americas continued this process, as the United States under President Thomas Jefferson sponsored Lewis and Clark's expedition over North America, part of whose mission was the gathering of natural history specimens and geographical information. Scientific societies cooperated in making and recording observations on a global basis, as in the famous transits of Venus across the face of the sun in 1761 and 1769.

The growth of the scientific sector led to an increase in the number of scientific professionals.

Professionalization narrowed the range of voices participating in science, as a pronounced division between "amateur" and "professional" scientists began to emerge. The ideal of the "amateur" scientist persisted longer in England, lacking either the German and Scottish university culture or the French scientific bureaucracy. However, even the Royal Society, a bastion of scientific amateurs, was feeling the pressure of professionalization by the early nineteenth century. Some entire populations found themselves barred from the new scientific professions, the most obvious example being women and persons of non-European descent. Scientific professionalization along with the growing volume of knowledge that a budding scientist had to absorb also led to a growing gap between working scientists and scientific popularizers.

Scientific societies and government agencies were more important for science than universities in most countries. Partial exceptions were Scotland and Germany, where many leading scientists were university professors. The leading scientific societies outside Britain and France included the Berlin Academy, the Imperial Academy of Sciences of St. Petersburg, the American Philosophical Society of Philadelphia, and the Royal Swedish Academy of Sciences in Stockholm. Informal groups, such as the Lunar Society of Birmingham and France's high-powered Society of Arcueil (1807–1813), were also important in the development of science.

Although scientists were growing more removed from the general population, science and scientific innovation began to attract more broad cultural attention. Enlightenment and the belief in progress provided powerful motivations for the popularization of science. Electrical science, which underwent several advances in this period including Alessandro Volta's invention of the battery, was particularly suited for dramatic experiments and presentations. Although the practice of European science remained heavily dominated by male Christians, its audience at least broadened considerably during the Enlightenment. Scientists, particularly those like the English chemist Humphry Davy

who possessed a flair for showmanship, could both inspire and capitalize on popular celebrity. Even less creative scientists could make careers for themselves as popularizers.

The general popularity of science in the Enlightenment was challenged by the rise of romanticism. Conservative Romantics like Joseph de Maistre believed that arrogant scientism helped cause the disasters of the French Revolution. Another Romantic critique of science emerged in Britain in response to the early Industrial Revolution. The destructiveness and economic injustice of early industrialism was blamed on the habits of mind—rational, calculating, selfish—fostered by science. This Romantic mistrust of technology, science, and scientists was memorably expounded in Mary Shelley's classic *Frankenstein* (1818), whose hero's inability to combine his scientific genius with understanding of the heart leads to his doom.

In 1750, French scientists possessed by far the most formidable apparatus for the support of science in Europe's most powerful and wealthy state. French was the language of international scientific communication, although it had not entirely displaced Latin. Paris, the home of the Royal Academy of Sciences and many other scientific associations and institutions, was the capital of European science. Much of this predominance was lost with the French Revolution of 1789. The revolutionaries eliminated many scientific institutions, including the Royal Academy of Sciences. Some important French scientists lost their lives in the revolution, most notably the chemist and tax farmer Antoine-Lavoisier.

However, the revolution was more of an interruption in the French predominance than its downfall. Lavoisier's execution did not stop the triumph of his theories. The revolutionaries, and their successors in the Napoleonic period, did provide much employment for physical scientists in practical concerns, from the vast project for creation of new weights and measures, which resulted in the metric system, to supervising the manufacture of gunpowder for the revolutionary armies. The revolutionaries founded new institutions, including the Institute of France, the Museum of Natural History, and the Ecole Polytechnique, a European center of

mathematical research. Paris under Napoleon bloomed again as an international scientific capital, as in addition to French scientists such as the mathematician and cosmologist Pierre-Simon Laplace Napoleon actively recruited foreigners such as the American Loyalist physicist Benjamin Thompson, Count Rumford. The social mobility opened up by the revolution also paved the way for many younger scientists, including the zoologist Georges Cuvier and the chemist Joseph-Louis Gay-Lussac. Even cooperation with scientists in hostile nations did not entirely disappear, thanks in large part to Joseph Banks, head of the Royal Society from 1780 to 1820.

—William E. Burns

Science in China in the Eighteenth Century

Science in China, as in Europe, evolved along lines that reflect the ideological and material interests of those with the time to pursue it and the money to fund it. In eighteenth-century China, scientific knowledge, or what might be better identified as natural studies, developed from

Chinese map of the Eastern hemisphere, made for the Qing court, 1790. (Bildarchiv Preussischer Kulturbesitz/Art Resource, NY)

THE QIANLONG EMPEROR AND TECHNOPHOBIA

At the end of the eighteenth century the English king sent an embassy that was received by Qianlong. George III asked for expanded trade, and Qianlong answered in the form of a letter delivered by Lord Macartney. In the letter the emperor replied, “We have never valued ingenious articles, nor do we have the slightest need of your country’s manufactures.” This quote has been used by Europeans to demonstrate Chinese xenophobia and a nonprogressive attitude toward the technology and the science of Europe. But Qianlong wrote these words at the end of his life after conquering massive territories in central Asia with the help of European Jesuit cartographers and weapons experts. Qianlong, a Manchu emperor of a Chinese civilian state, was unwilling to admit interest in foreign technology since it would demonstrate weakness both domestically and internationally. Moreover, most of the manufactures brought as gifts in 1793 were not marketable in China, and the advanced weapons technology that would have interested Qianlong was excluded. Many Chinese and European documents from the eighteenth century demonstrate an ongoing exchange of technical and scientific information between China and Europe.

three interrelated factors: the long, expansive reign of the Qianlong emperor (1736–1796); the diminishing but still important European Jesuit presence as court mathematicians, astronomers, and cartographers for Qing imperial expansion; and the growth of an empirical scholarly community that moved away from moral studies toward evidential studies (*kao zheng xue*) of classical texts, philology, mathematics, and astronomy. Nonmilitary technological advances in China, as in Europe, were usually made by semiliterate clerks and craftsmen on the margins of society who could not read the texts written by elites.

The emperor supported astronomical research because making an accurate calendar that

governed plantings and harvest prevented famine and peasant uprisings that would threaten his rule. Mapmaking enabled administrators to govern and generals to wage the wars of conquest and consolidation that nearly doubled the area of the empire during the century. Qianlong’s generals brought Jesuits with technological expertise on many of their military expeditions, taking advantage of their skills in cartography and weapons-casting technology to oversee the use of heavy artillery. At the beginning of the eighteenth century, the missionary work of the Jesuits was proscribed by the Qing emperors, but a small number, together with their Chinese converts, dominated the Astro-calendric Bureau and the Academy of Mathematics until the Jesuit order was suppressed by the pope in 1773.

Chinese court scholars such as mathematician Mei Wending (1633–1721) and encyclopedist Chen Yuanlong (1652–1736) incorporated Jesuit Western learning (*Xixue*) into Chinese learning, revived the study of China’s own ancient mathematical and medical traditions, and made significant claims for Chinese origins of Western learning in books such as Chen’s *Mirror Origins of Scientia* (1735). In 1715 the Kangxi emperor banned questions about astronomy, astrology, and music in the imperial examinations, encouraging two related trends. Scholars in the extremely competitive examination system focused on exacting research in phonology, paleography, and etymology to seek truth from facts in the classic Confucian texts, while the growing number of scholars in the rich South Yangtze region who could not attain official positions developed a world of independent scholarship that continued to touch on scientific topics. This work of official and nonofficial exacting scholarship continued under further generations of evidential studies scholars such as Dai Zhen (1724–1777), Qian Daxin (1728–1804), and Ruan Yuan (1764–1849). One of the most interesting products of this century was Qian and Ruan’s *Biographies of Astronomers and Mathematicians* (1799), which summarized the works of 280 scientists, including 37 Westerners such as Nicolaus Copernicus (1473–1543) and missionaries to China such as Jesuit Matteo Ricci (1552–1610). This book demonstrated the integration of science with evidential studies at the end of

the century and laid the foundation for the next great contact between Chinese and Western learning in the nineteenth century.

Chinese scholars in the eighteenth century assimilated learning from the West with caution, partly because seventeenth-century Jesuits had misrepresented the heliocentric astronomy of Copernicus and Galileo for religious reasons. Galileo's version only reached China in the mid-eighteenth century, causing confusion. While this miscommunication may have led to limits in the development of science in China, it is far more interesting to ask what did happen in natural studies and technology, separated as their centers of activity were, than it is to ask the old question of why a scientific revolution did not happen in China.

Scientific Academies in Europe

Academies and scientific societies dominated institutional science in the eighteenth century more than ever before or since. Virtually every male scientist of importance was a member or correspondent of at least one scientific society. (Women, with very few exceptions, were barred from membership.) Society memberships were an important way of establishing one's standing as a member of the scientific community and were frequently listed after the author's name on the title pages of their books.

A scientific society's formal chartering often occurred after years of informal meetings rather

than simply being created by a government. Academies differed from informal gatherings in that they had written rules, a fixed meeting schedule, defined membership, and their own quarters. They usually had libraries and collections of curiosities and scientific implements. Scientific academies were often charged with government functions such as overseeing observatories or advising the government on scientific and technological questions. Major societies and many minor ones also sponsored periodical publications such as the Royal Society's *Philosophical Transactions* and prize competitions. Scientific societies were only part of Europe's growing array of learned institutions, and often a scientific society existed as one part of a large academy devoted to other topics as well, such as literature and industry. Groups exclusively devoted to science were usually found where there was a large concentration of resources, such as the national capitals of Europe's most powerful states. Other specialized societies, such as societies for medicine, technology, and economic development, also had scientific interests.

The two most important scientific societies were the oldest, Britain's Royal Society and France's Royal Academy of Sciences, both founded in the 1660s. They presented strikingly different organizational models. The Royal Society did not have a fixed number of members, was open to full membership by nonscientists, and lacked an internal hierarchy among its fellows, all of whom were theoretically equal and none of whom were paid. The Royal Academy had a limited membership, and salaried members were divided into a hierarchy of classes. The Royal Society supported its activities through dues and other internal sources, while the Royal Academy was supported by the state. Most European scientific societies were organized like the Royal Academy. Close behind these two in the institutional hierarchy were the Imperial Academy of St. Petersburg, the Berlin Academy, and the Royal Swedish Academy of Sciences.

Academies formed a network with overlapping memberships and exchanges of periodicals and information. Serious cooperation between scientific academies in joint scientific endeavors began in the 1750s and 1760s with programs to observe the transits of Venus across the face

➤ JOSEPH BANKS

Joseph Banks (1743–1820), explorer, collector, and president of the Royal Society for more than four decades, dominated the public face of late-eighteenth-century and early-nineteenth-century English science. From a rising family of lawyers and gentry, Banks made his scientific reputation by accompanying Captain James Cook in the *Endeavour* voyage in the South Pacific from 1768 to 1771 as a natural historian and representative of the Royal Society. Banks made enormous collections and kept a voluminous journal of his observations, not published until the twentieth century. (Banks published very little, mostly because of his own reluctance.) On his return to England he became the great celebrity of the voyage.

In 1778 Banks was elected president of the Royal Society, a position he held the rest of his life.

He was a successful but controversial president. His strengths were his conscientious devotion to duty and an amazing capacity for work. The letters he wrote and received in his presidency number well over 100,000. His greatest achievement as a scientific statesman was maintaining connections between British and Continental scientists during the Revolutionary War and the Napoleonic Wars. On occasion he intervened to procure the release of British savants held by the French and French scientists held by the British. Banks's weakness, which increased with age and gout, was an autocratic temperament. He was also seen as an obstacle by people who wanted to reform the Royal Society to make it a strictly professional group composed only of scientists.

—William E. Burns

of the sun from various positions all over the world. The second set of transit observations, in 1769, was particularly noteworthy for the participation of Philadelphia's American Philosophical Society, the first successful effort to transplant the scientific academy across the Atlantic.

Although many societies had lost vitality by the late eighteenth century, what ended the age of scientific societies was the French Revolution, which boldly abolished the Royal Academy of Sciences along with every other academy in Paris and the provinces in 1793. The objection to the academies was that they were aristocratic and elitist and kept knowledge from the people. The Royal Academy was restored two years later in the form of the first section of the Institute in France, but the provincial academies were not revived until after Napoleon's fall in 1815 and never regained their prominence. The Revolutionary War and the Napoleonic Wars with their accompanying devastation also forced several continental scientific societies to close their doors, either temporarily or permanently. Another long-term menace was the rise of smaller specialized societies. Such societies created in the early nineteenth century included France's Society of Arcueil, an elite but short-lived group specializing in physics and chemistry, and Britain's Geological Society, founded in 1807 by

British geologists who believed that the Royal Society was insufficiently attentive to their science. Despite Royal Society opposition, the new society proved a great success.

European Advances in Chemistry

Chemistry underwent the most profound changes of any science during the Enlightenment. Its vocabulary, subject matter, range of available procedures, and fundamental theories all were vastly altered, and its position within the world of science moved from marginal to central.

The most important development in the mid-seventeenth century was the chemical analysis of the air. Traditionally, air had been considered a single element. The center of the new research into pneumatic chemistry was Great Britain. The first distinct air to be separated and identified was carbon dioxide, which the Scottish professor Joseph Black produced in a series of experiments he performed on magnesium carbonate and called fixed air. Henry Cavendish isolated hydrogen (inflammable air) in 1766 and also devised a way of holding gases over liquid mercury rather than water, ending the problem of their dissolution in water. Daniel Rutherford (1749–1819) identified nitrogen in 1772. Joseph Priestley discovered many types of air, the most important being dephlogisticated air, later named oxygen by Antoine-Laurent Lavoisier.

Lavoisier is associated with the revolutionary discovery that combustion was a combination of fuel with oxygen rather than a release of phlogiston. Along with Cavendish, Lavoisier also introduced more precise weight measurement and mathematical rigor into chemistry. He began to reform chemical terminology into a more rational system based on elements and championed the idea that any substance with enough heat could become a gas, or the theory of the gaseous state. Lavoisier also introduced several new pieces of equipment, such as the calorimeter to measure heat.

Lavoisier's theory vanquished its rivals by the close of the eighteenth century, and chemistry continued its rapid development. Romantics, both British and Continental, promoted chemistry, seen as a science of dynamic and mysterious forces, as compared to deterministic physics and mechanics. Important early-nineteenth-century developments included the refutation of Lavoisier's theory that oxygen was the cause of acidity, the rise of electrochemistry, and John Dalton's chemical atomism. The Italian Alessandro Volta's generation of electricity by the juxtaposition of different metals (silver and zinc) in 1800 led to the science of electricity becoming more closely allied to chemistry. The English experimenter Humphry Davy adapted the newly invented voltaic pile, or battery, to chemical analysis. His first great triumph was the decomposition of water into hydrogen and oxygen in 1801. Dalton's

Apparatus used by Antoine Laurent Lavoisier to study chemical reactions in the combustion of substances, 1789. (Library of Congress)

➤ ANTOINE-LAURENT LAVOISIER

Unlike many aspiring scientists, the French aristocrat Antoine-Laurent Lavoisier (1743–1794) was not driven by financial ambition. Already very wealthy, he invested in the Farmers-General, a group that subcontracted tax collection from the government. The most important contribution that the Farmers-General made to Lavoisier's scientific life was a Farmer's daughter, Marie-Anne Pierrette Paluze (1758–1836), whom he married in 1771. Madame Lavoisier was useful as an assistant, an illustrator of his books, and a translator; despite his interest in British chemistry, Lavoisier never learned English.

Lavoisier's most important chemical discovery was that combustion was the combination of the burning substance with a gas he called oxygen. His *Elementary Treatise of Chemistry* (1789) set forth his controversial theories. Lavoisier's capacity for work was astounding. In addition to his experiments and many tasks for the Academy of Sciences and the Farmers-General, he was appointed to several government commissions and ran his estate at Frechines as an experimental farm. Lavoisier originally supported the French Revolution and fought long and hard, but ultimately in vain, to save the academy from the revolutionary government. He was executed for his role in the unpopular Farmers-General, which the revolution had abolished.

—William E. Burns

New System of Chemical Philosophy (1808) asserted that all basic elements were composed of tiny particles, or atoms, and that they combined in fixed ratios to form compounds. Elemental atoms were both indestructible and could not be created, and they could not be transmuted into another element. Atoms of different elements had different weights. The atoms of elements combined to form what Dalton called compound atoms and what we now call molecules.

Biology in the Age of Reason

Eighteenth-century European scientists described and classified living things to an unprecedented degree but also questioned the nature of life and reproduction itself. Numerous life forms from all over the world were cataloged, and many found a place in Europe's expanding system of botanical gardens and zoological collections. By the early 1800s the term "biology" had been coined for the science of living things.

Botany evolved in the eighteenth century from a branch of medicine principally concerned with plants' medicinal uses to an independent science. Botanists were particularly challenged by the thousands of new plants and plant descriptions reaching Europe from explorers and botanical expeditions all over the globe. The necessity of finding a place for all of this information made a workable system of plant classification, for which scientists had been striving since the sixteenth century, even more urgent. The Swedish botanist Carl Linnaeus became one of the most influential scientists of the century by inventing a popular classification scheme, the sexual system of Linnaeus, based on the number and arrangement of a plant's sexual organs. Linnaeus's disciples applied his system to plants in many countries. His system was rivaled by natural classification, a predominantly French technique that looked at the whole plant. The natural classifiers had the support of the powerful French Royal Botanical Gardens. In the early nineteenth century natural classification displaced Linnaean classification among professional botanists. Classification was not the only area of botanical advance. Plant sexuality, still controversial at the dawn of the eighteenth century, became better understood, as did plant physiology, the study of how plants absorb nutrition from the air and ground.

Zoology did not attract as much interest as botany. The most important zoologists were French, including the Comte de Buffon and Georges Cuvier and Jean-Baptiste Lamarck at the Paris Museum of Natural History in the

LAZZARO SPALLANZANI REFUTES SPONTANEOUS GENERATION

The Italian cleric and university professor Lazzaro Spallanzani (1729–1799) was the most meticulous and creative biological experimenter of the Enlightenment. His concern for experimental technique enabled him to refute the English experimenter John Turberville Needham's defense of spontaneous generation. Needham boiled beef broth for a few minutes, then put it in a flask sealed with cork. He claimed that boiling killed any germs in the broth, and sealing prevented other germs from entering. When the flasks were opened later and

microscopic examination found living organisms, they were proof of spontaneous generation. Spallanzani showed that by boiling it for a longer time and using hermetically sealed glass, the broth or any other liquid remained free of organisms, thus disproving spontaneous generation. However, Needham and his supporters claimed that prolonged boiling destroyed the liquid's ability to generate life, and the controversy remained unsettled.

—William E. Burns

Revolutionary and Napoleonic periods. The great systematic works of Cuvier and Lamarck provided a superior organizational scheme for information about animal species. Scientists debated whether it was possible for a species to become extinct or to evolve. Animal anatomy, or comparative anatomy, was no longer practiced mainly by physicians hoping to better understand human anatomy but instead became an autonomous enterprise. Cuvier, the first major comparative anatomist without a medical education, also broadened the science by studying fossils as well as living species.

The nature, or even the existence, of the distinction between living and nonliving things presented many problems as the old debate over whether living things could be spontaneously generated from nonliving material continued. The question of whether animals reproduced by forming a new individual from scattered parts (epigenesis) or whether each began as a fully formed miniature in its mother's egg or father's sperm (preformationism) also provoked passionate controversy.

Scientific and Technical Education under Napoleon

One of Napoleon's most long-lasting legacies to France was his reorganization of the educational system. The French Revolution had destroyed the old Church-dominated educational system but put little in its place. The creation of the most centralized system of education the world had ever seen began with the promulgation of the law on public instruction in 1802. This created a system of elite secondary schools called lycées controlled from Paris. At these schools boys were taught a traditional curriculum built

Napoleon visiting the École Polytechnique in Paris, nineteenth-century illustration. (Photo12/The Image Works)

around the classics and mathematics. Napoleon's centralization of education continued with the founding of the Imperial University in 1807. The term "university" is misleading, as the Imperial University was actually a centralized bureaucracy charged with overseeing all instruction in France. Several of France's leading scientists, particularly the chemist Antoine-François de Fourcroy and the naturalist Georges Cuvier, helped devise the reformed educational system or worked in it. However, the reformed system was criticized for its traditional curriculum based on the classics and French literature with comparatively little emphasis on science and mathematics. Much of this was due to the influence of the first master of the university, Louis de Fontanes, who as a conservative Catholic and opponent of the Enlightenment promoted the study of Greek and Latin over science and mathematics.

The density of educational and scientific institutions in Paris and the practice of one scholar holding multiple positions at different institutions enabled the city to support a remarkably large number of both senior and junior scientists. The elite Parisian institutions incorporated into the new educational system included the Ecole Polytechnique, Europe's leading mathematical and engineering institution, founded in 1794 and relocated and made into a military institution by Napoleon in 1805. (Numerous military academies, including the United States

▶ NAPOLEONIC ESTABLISHMENT OF LYCÉES

Excerpt from Title IV of the law on public education promulgated in 1802 setting up the lycées:

“9. Lycées shall be established for instruction in letters and the sciences. There shall be at least one lycée for each tribunal of appeal district.

10. Instruction shall be given in the lycées in the ancient languages, rhetoric, logic, ethics, and the elements of the mathematical and physical sciences.

The number of professors in the lycée shall never be less than eight; but it can be increased by the government, as well as the number of the subjects of instruction, according to the number of pupils who shall attend the lycées.

11. There shall be in the lycées, study masters, and masters of drawing, military exercises, and of accomplishments.”

—William E. Burns

Military Academy at West Point, founded in 1819, would be modeled on the École Polytechnique.) Distinguished professors at the Polytechnique included the mathematicians Gaspard Monge and Joseph Fourier.

Napoleon and the educational elite took little interest in the education of women, who

they believed should be educated only enough to function as wives and mothers. What little science and technology was formally taught to women was oriented to the household. The one exception was the first national institute anywhere for teaching midwives, founded in 1807 and headquartered in Paris, that taught herbal medicine and vaccination as well as midwifery.

Like previous French rulers, Napoleon hoped that science could contribute to economic development. Among his ideas was a system of institutions to train 100 chemists in improved means of extracting sugar from sugar beets, hoping to make France self-sufficient in sugar. Napoleon fell from power before these institutions were set up, and France went back to importing cane sugar.

■ Introduction: Europe’s “Second Scientific Revolution”

Europe’s first scientific revolution is conventionally dated from 1543, when the Polish astronomer Nicolaus Copernicus in his *On the Revolution of the Heavenly Spheres* challenged the geocentric theories of the universe set forth in antiquity by Aristotle and Ptolemy. This scientific revolution came to a climax in 1687, when the English mathematician and scientist Isaac Newton outlined his theory of the law of universal gravitation in his *On the Mathematical Principles of Natural Philosophy*. In the century and a half between the publication of these two books, mathematicians developed

coordinate geometry and calculus (infinitesimal and differential) and made important breakthroughs in the areas of probability theory, number theory, algebra, and mathematical notation. Physicists discovered the laws of mechanics, astronomers confirmed the reality of heliocentrism, and “building on the shoulders of giants” Newton showed how the physical laws determining earthly motion and the laws determining planetary motion were two different expressions of the same law, that of universal gravitation. In the words of Alexander Pope, England’s greatest eighteenth-century poet,

"Nature and Nature's laws lay hid in night.
God said, Let Newton be! And all was light."

To the thinkers of the eighteenth-century Enlightenment there was no more convincing proof of the regularity of the laws of nature and the power of human reason than the achievement of seventeenth-century science.

A second scientific revolution took place in Europe in the nineteenth century. Progress in physics, astronomy, and mathematics continued, but more rapid and impressive strides were made in chemistry, biology, geology, genetics, and the study of electricity, magnetism, and heat. Scientists carried on their research in new institutional settings. The leading figures of the first scientific revolution were self-taught in the sense that universities and schools offered little in the way of scientific and mathematical training. Many scientists worked in isolation, with their memberships in a small number of scientific societies providing the only opportunities for sharing their findings through publication. Beginning with the foundation of the *École Polytechnique* in revolutionary France in 1794, a number of states founded special institutions where experts in their fields trained future scientists. Beginning in the 1820s, German universities paved the way by offering scientific training not only for professional scientists but also for future pharmacists, teachers, physicians, and civil servants. As the German model spread, university laboratories became important centers of scientific research, the results of which were published in journals sponsored by new professional societies linked to specific subdisciplines.

Another feature of science in the nineteenth century was the new bond between the sciences and technology. Despite the invention of the telescope by Galileo and of the microscope by von Leeuwenhoek, the breakthroughs in the first scientific revolution had not been dependent on new instrumentation or equipment. Furthermore, although the discoveries of the age had profoundly affected the perceptions of intellectuals, they had had little impact on how humans lived their daily lives. Nineteenth-century science relied on more accurate instruments for measuring time, weight,

heat, electrical currents, magnetic force, the chemical composition of materials, and radiation. More importantly, science contributed to the many technological innovations of the period. Basic scientific research made possible the telegraph, the telephone, chemical fertilizers, a host of electrical devices, countless new industrial processes, and new medical techniques and treatments.

Science in the nineteenth century continued to affect how humans perceived their world. Just as the acceptance of Newtonianism in the eighteenth century had strengthened the belief in human reason and the idea of a mechanical universe running according to a few basic principles, Darwinism in the nineteenth century focused attention on the importance of change, raised unsettling religious issues, and affected political and social ideologies. It also reinforced the idea of progress.

Then around 1900 the second scientific revolution came to an end. After a decade in which many assumptions about matter, energy, light, and the universe were called into question by new observations and experiments, science entered another period of rapid change in which concepts such as curved space, relativity, special relativity, a fourth dimension, and the space-time continuum forced scientists and laypersons to discard long-held conceptions. A new revolution, the Einsteinian Revolution, had begun.

—James H. Overfield

The New Physics—The Curies, Rutherford, Maxwell, Planck, and Einstein

Physics, the branch of science that deals with matter and energy and their interactions, underwent fundamental changes and achieved spectacular results in the nineteenth century. Discoveries relating to the nature of light, heat, electricity, magnetism, and the makeup of matter itself resulted not only in new theoretical insights but also in practical discoveries that served the commercial, military, and political needs of an increasingly industrialized society. The most spectacular breakthroughs occurred at the close of the nineteenth century and the beginning of the twentieth century, but these

James Maxwell was a Scottish physicist who is best known for his formulation of electromagnetic theory and for his research on electricity and magnetism. (Oxford Science Archive/StockphotoPro)

achievements were based on foundations laid earlier in the 1800s.

A key advance occurred in the 1830s when the British physicist Michael Faraday (1791–1867) demonstrated that electricity and magnetism are two aspects of the same phenomenon. Following up his insight, Scottish physicist James Clerk Maxwell (1831–1879) observed, as had Faraday, that magnetism does not end at the edge of a magnet but instead travels through space to attract, for example, an iron nail. If it were linked with magnetism, electricity must likewise travel through space and not just through a metal or an ionic solution. Moreover, Maxwell demonstrated in a series of papers in the 1860s that electricity and magnetism, electromagnetic radiation, were a type of light. It was obvious that light travels through space, but Maxwell did not consider this space empty. A tenet of physics held that light was a wave. Maxwell knew that sound also was a wave and that it did not travel through a vacuum. Rather, sound needed a medium (air, for example) through which to travel. Light must by analogy also need a medium through which to travel. Following convention, Maxwell identified this medium that permeated all space as the ether.

In revolving around the sun, Earth must move through the ether, causing a drag analogous to the drag one experiences in pedaling a bicycle into a headwind. A wave of light moving into the ether should slow down from the drag, yet all efforts in the late nineteenth century failed to detect a reduction in the speed of light. No matter in which direction it traveled, light held a constant speed.

This led Swiss physicist Albert Einstein (1879–1955) in 1905 to deny the existence of the ether and to assert that the speed of light is

always constant. Tame as these claims may seem, the second of them revolutionized the concepts of time, space, and matter. Time, Einstein calculated, ticks slower the nearer one approaches the speed of light until at light speed it stands still. The length of an object decreases the nearer one approaches light speed, whereas paradoxically its mass increases. At light speed the mass of an object is infinite, implying that infinite energy is necessary to accelerate an object to light speed. Because it is impossible to harness infinite energy, an object cannot reach light speed, which must therefore be the maximum speed in the universe. In Einstein's physics, time, space, and matter are not the absolutes that common sense supposes them to be but instead are relative to the observer who measures them.

The impossibility of harnessing infinite energy did not prevent Einstein in a second paper in 1905 from quantifying a new relationship between energy and matter. He calculated that energy and mass (the measure of matter) are interconvertible, according to the equation $E=mc^2$. Because c^2 equals 90 million billion meters per squared second, a tiny mass yields enormous energy.

In a third paper in 1905 Einstein returned to an old problem of thermodynamics, blackbody radiation. In the late nineteenth century German physicist Gustav Robert Kirchhoff (1824–1877) conceived of an object (a blackbody) that radiates all the energy it receives as heat. Kirchhoff and other physicists were puzzled that mathematical equations could approximate but could not describe with precision the energy released as heat in experiments. In 1900 German physicist Max Planck (1858–1947) harmonized experiment and equation by assuming that a blackbody absorbs energy and radiates heat not as a continuum but in discrete units that he called quanta. In 1900 Planck may have viewed quanta as nothing more than a mathematical convenience, but Einstein was quick to apply the new quantum theory to light. Einstein demonstrated that light could knock electrons from a metal with some multiple of a quantum in energy. He interpreted this phenomenon as evidence that light radiates energy in quanta and thus is a composite of particles, each a quantum. In addition to being a wave, light was also a particle.

► PIERRE CURIE DESCRIBES THE DISCOVERY OF RADIOACTIVITY

This excerpt comes from Pierre Curie's 1905 Nobel lecture in Stockholm. The lecture was delivered two years after Pierre and Marie Curie had won the Nobel Prize in Physics (along with Antoine Henri Becquerel), as the Curies were not able to come to Stockholm in 1903 due to teaching obligations and poor health.

"Becquerel discovered in 1896 the special radiating properties of uranium and its compounds. Uranium emits very weak rays which leave an impression on photographic plates. These rays pass through black paper and metals; they make air electrically conductive. The radiation does not vary with time, and the cause of its production is unknown.

Mme. Curie in France and Schmidt in Germany have shown that thorium and its compounds possess these same properties. Mme. Curie also showed in 1898 that of all the chemical substances prepared or used in the laboratory, only those containing uranium or thorium were capable of emitting a substantial amount of the Becquerel rays. We have called such substances *radioactive*. . .

Mme. Curie has studied the minerals containing uranium or thorium, and in accordance with the views just stated, these minerals are all radioactive. But . . . she found that certain of these were more active than they should have been according to the content of uranium or thorium. Mme. Curie then made the assumption that these substances contained radioactive chemical elements which were as yet unknown. We . . . have sought to find these new hypothetical substances in a uranium ore, *pitchblende*. By carrying out the chemical analysis of this mineral and assaying the radioactivity of each batch separated in the treatment, we have . . . found a highly radioactive substance with chemical properties close to bismuth which we have called polonium, and then . . . a second highly radioactive substance close to barium which we called radium."

Einstein and Planck were two of many physicists to focus on energy. In 1896 French physicist Antoine-Henri Becquerel (1852–1908) had discovered that uranium spontaneously emits energy. In 1898 Polish physicist Marie Curie (1867–1934) identified thorium as likewise radioactive, and later that year she and her husband Pierre (1859–1906) added polonium and radium to the roster of radioactive elements. In 1902 British physicist Ernest Rutherford (1871–1937) discovered that a radioactive element emits, in addition to energy, two types of particles, helium nuclei and electrons, alpha and beta particles, respectively. In releasing an alpha particle a radioactive element transmutes into a lighter element. Uranium, for example, degrades into thorium.

Rutherford was interested not only in radioactivity but also in the structure of an atom. His assistant Johannes Hans Geiger (1881–1945) demonstrated that an atom could deflect an alpha particle fired at it. This result led Rutherford in 1911 to envision an atom as largely empty space

except at the core, which was a nucleus containing nearly all the mass of an atom. Electrons must occupy the empty space and in some fashion revolve around the nucleus. This nuclear model of the atom replaced the view that an atom was a more or less uniform distribution of matter.

These advances in physics ushered in the nuclear age in the twentieth century. During World War II physicists in the United States would use $E=mc^2$ to calculate the energy released in a nuclear explosion. After the war the equation would describe the energy that a nuclear plant produces and that the sun radiates to sustain life on Earth.

Biology

In 1750 the activities of those who studied life were too diverse to lend a simple definition to what they did. The term “biology” did not exist. To be sure, the disciplines of botany and zoology had long existed, but they comprised only part of the modern science of biology. In 1750 the term closest in meaning to biology was “natural history,” which in the eighteenth century united the scientists, philosophers, physicians, clerics, and amateur enthusiasts who studied life. Often indistinct from natural theology, natural history had in 1750 emancipated itself from neither theology nor geology. It was an eclectic science that included people who studied nature to clarify the relationship between God and his creation, those who studied rocks and the fossils, and others who studied life for the purposes of medicine or physiology.

Gregor Mendel, the nineteenth-century Augustinian friar known as the “father of genetics,” proved that the inheritance of traits follows particular laws. These laws, known as Mendel’s Laws of Inheritance, became the cornerstone of genetic research in the early twentieth century. (William Bateson, *Mendel’s Principles of Heredity: A Defence*, 1902)

The Enlightenment began to drive a wedge between natural history and natural theology and in doing so asserted the independence of natural history. French philosophe Denis Diderot (1713–1784) rejected the claim of spiritualists that a vague vital force animated life and asserted that life is the sum of purely physical processes. Affirming Diderot and taking their cue from the work of Italian physician Luigi Galvani (1737–1798), who caused muscular contractions in frogs’ legs by applying static electricity, some nineteenth-century scientists theorized that electricity was the physical force that animates life.

The casting out of vitalism began to transform natural history into a secular pursuit. Conscious of this development, French evolutionist Jean Baptiste Lamarck (1744–1839) in 1801 coined the term “biology” for the activities that had once gone by the rubric of natural history. Important as the change in terminology was, it could not separate biology, at least in the short term, from its past as an endeavor of amateurs. Charles Darwin (1809–1882), the century’s greatest biologist, remained all his life an amateur naturalist with no formal connection to a museum or university. Gregor Mendel (1822–1884), the famed Austrian botanist who discovered the basic laws of heredity, also was an amateur. A member of the Augustinian religious order, Mendel based his studies on peas in his monastery’s garden and gave up science altogether when he was chosen abbot of his monastery in 1868.

Both Darwin and Mendel figured prominently in the development of biology. Darwin had been one of many scientists in the nineteenth century to cast about for the source of variation in life. It had been plain for millennia that two organisms are seldom alike in every particular. Even identical twins manifest differences in behavior. Yet while Darwin and legions of others puzzled over why organisms vary, the answer was close at hand. In 1865 Mendel published the results of experiments in crossbreeding peas. Mendel asserted that peas are bundles of units, what biologists now call genes. These genes code for characteristics: the height of pea plants and the color of peas, for example. Pea plants vary from one another because they differ in their genes. An important corollary is that pea plants with the same genes should be identical.

➤ MENDEL'S DISCOVERIES ARE DISCOVERED

The following is a quotation from *Heredity and Sex* by Thomas Hunt Morgan (1913) about the discovery of Mendel's research after decades of obscurity.

"The modern study of heredity dates from the year 1865, when Gregor Mendel made his famous discoveries in the garden of the monastery of Brunn. For 35 years his paper on heredity, embodying the splendid results of his work, remained unnoticed. It suffered the fate that other important discoveries have sometimes met. In the present case there was no opposition to the principles involved in Mendel's discovery, for Darwin's great work on 'Animals and Plants' (1868), that dealt largely with problems of heredity, was widely read and appreciated. . . .

In 1900 three botanists were studying the problem of heredity. Each obtained evidence of the sort Mendel had found. Happily, Mendel's paper

was remembered. The significance of his discovery now became apparent. De Vries, Correns, and Tschermak brought forward their evidence in the same year (1900). Which of the three first found Mendel cannot be stated, and is of less importance than the fact that they appreciated the significance of his work, and realized that he had found the key to the discoveries that they too had made. From this time on the recognition of Mendel's discovery as of fundamental importance was assured. Bateson's translation of his paper made Mendel's work accessible to English biologists, and Bateson's own studies showed that Mendel's principles apply to animals as well as to plants."

Thomas Hunt Morgan, *Heredity and Sex* (New York: Columbia University Press, 1913), 73–75.

The environment must be responsible for differences in pea plants with the same genotype. Mendel's work implied that although the environment can affect the characteristics of a pea plant, the environment cannot change a gene. (Mendel did not allow for mutation.) Constant in coding for characteristics, genes pass from parents to offspring through reproduction and are thus the material of heredity. Mendel's insights are the foundation of genetics, but biologists in the late 1800s ignored him, perhaps because he published little.

Ignorant of Mendel, biologists approached the problem of heredity from cytology. In 1887 Belgian cytologist Edouard Beneden discovered meiosis. Whereas somatic cells double the number of chromosomes before they divide, a process called mitosis, the cells that produce gametes hold the number of chromosomes constant before they divide. In dividing, therefore, these cells halve the number of chromosomes. A gamete, having half the number of chromosomes in a somatic cell, unites with another gamete in fertilization to restore the full number of chromosomes.

Beneden's discovery of meiosis focused attention on the chromosomes and implied that

they had a role in heredity. The issue crystallized in 1900 when three botanists independently rediscovered Mendel's paper on pea hybridization. Quick to infer the link between chromosomes and genes, American cytologist Walter Sutton in 1903 and German zoologist Theodor Boveri in 1904 asserted that chromosomes and genes are not identical structures. Instead chromosomes contain genes.

The organization of genes on a chromosome remained murky until American embryologist Thomas Hunt Morgan (1866–1945) and his students at Columbia University in 1909 began crossbreeding fruit flies. Their discovery that genes for eye color are on a sex chromosome led Morgan to envision a gene as a particle and to seek to fill in the places of these particles on a chromosome. Further experiments confirmed that a chromosome is a linear arrangement of genes. In this work Morgan united the gene and chromosome theories.

Morgan's achievements underscore the degree to which biology had changed between the mid-nineteenth and early twentieth centuries. By the early twentieth century the days had passed when a lone amateur such as Darwin or

Mendel could make fundamental contributions to biology. Biology now was a profession of specialists. Rather than the lone individual, the biologist had by the early twentieth century come to command a laboratory and graduate students. The institutionalization of biology placed biologists in the university, a particularly happy circumstance in the United States, where the land-grant colleges grew to absorb biologists in several specialties. Utilitarian in their function, these colleges called on biologists to conduct practical instead of theoretical research. Rather than constrain biology, the dictum of practicality yielded the discovery of Vitamin A and the breeding of hybrid corn by World War I.

Theories of Evolution before Darwin

The idea of biological evolution has a long history. Pre-Darwinian evolutionary theories differed from Charles Darwin's in being more likely to view evolution as aiming at a specific goal. In the eighteenth century the debate was couched in terms of those who upheld the idea of fixity of species (that a species could not change) versus those who believed that it could. Defenders of the latter idea included Charles Darwin's

grandfather, Erasmus Darwin, whose massive two-volume *Zoonomia* (1794, 1796) Charles read as a young man.

The most scientifically significant pre-Darwinian evolutionist, however, was the French naturalist Jean-Baptiste Lamarck. Lamarck's theory of evolution was based on the idea that living things responded to environmental changes by changing their forms, although he also drew on the idea of living things possessing an innate drive to perfection. He included the human species in his evolutionary scheme. Although the belief that acquired characteristics could be passed down to an organism's descendants became identified as Lamarckianism, this was a belief that Lamarck shared with others and was not central to his thinking. For both scientific and religious reasons, Lamarck's theory attracted few followers and many opponents. Lamarck showed little actual evidence of its operation, and there was much evidence against it, such as the lack of transitional forms in the fossil record. Some opposed what they saw as the theory's materialism and its denial of the necessity of a divine designer and creator.

The principal opponent of evolutionary theory in early-nineteenth-century France was the great comparative anatomist Georges Cuvier, a believer in the fixity of species. Cuvier, a master scientific politician, not only prevented Lamarck's theory from having much influence but also marginalized the other significant French supporter of evolution, Etienne Geoffroy Sainte-Hilaire.

In the early nineteenth century the spread of the geological idea that the Earth had existed for millions of years helped make evolutionary changes more intellectually acceptable. Evolutionary theory influenced by Lamarck was presented in Great Britain in the anonymous work *Vestiges of the Natural History of Creation* (1844), whose author was not a trained scientist but the Scottish publisher Robert Chambers, although his identity only became known after his death. The scheme of *Vestiges*, which sold many copies and provoked enormous controversy, incorporated cosmology and geology along with biology and the study of human society in a vast picture of a constantly progressing universe.

—*William E. Burns*

Jean-Baptiste Lamarck was a botanist and naturalist who proposed an early theory of evolution based on the doctrine of inheritance of acquired traits. Though Lamarck's evolutionary theory is now considered invalid, Charles Darwin, the father of modern evolutionary theory, credited Lamarck with laying the foundation for a new understanding of evolution. (Library of Congress)

► CHAMBERS ON EVOLUTIONARY PROGRESS

The following is an excerpt from Robert Chambers's anonymously written *Vestiges of the Natural History of Creation* (1844):

"In pursuing the progress of the development of both plants and animals upon the globe, we have seen an advance in both cases, along the line leading to the higher forms of organization. Amongst plants, we have first sea-weeds, afterwards land plants; and amongst these the simpler (cellular and cryptogamic) before the more complex. In the department of zoology, we see zoophytes, radiata, mollusca, articulata, existing for ages before there were any higher forms. The first step forward gives fishes, the humblest class of the vertebrata; and, moreover, the earliest fishes partake of the character of the next lowest sub-

kingdom, the articulata. Afterwards come land animals, of which the first are reptiles, universally allowed to be the type next in advance from fishes, and to be connected with these by the links of an insensible gradation. From reptiles we advance to birds, and thence to mammalia, which are commenced by marsupialia, acknowledgedly low forms in their class. That there is thus a progress of some kind, the most superficial glance at the geological history is sufficient to convince us."

Darwinism

Darwinism, named after English naturalist Charles Darwin (1809–1882), is one of several theories of evolution. Darwin's books *On the Origin of Species by Means of Natural Selection* (1859) and *The Descent of Man and Selection in Relation to Sex* (1871) brought evolution to the forefront of scientific, theological, and popular debate. The ensuing controversy soon polarized along liberal and conservative lines, with scientists, empiricists, and freethinkers generally accepting evolution while traditional religious thinkers rejected it in favor of either biblical creationism or intelligent design theory.

The first important theorist of evolution was French naturalist Jean-Baptiste Lamarck

(1744–1829). Lamarckism is the belief that environment determines inheritance. Individuals acquire characteristics by responding to their environment and then pass these characteristics to their offspring, thus creating mutations and eventually new species. Scottish geologist Charles Lyell (1797–1875) aroused British interest in evolution in the 1830s with his vigorous refutation of Lamarckism in his three-volume *Principles of Geology*. Lyell at first opposed all evolutionary theory as irreligious, but in the 1860s he became an advocate of natural selection and a strong ally of Darwin. Natural selection is the process by which stronger and better-adapted individuals live longer and reproduce more successfully than weaker or less well-adapted individuals. Darwin's theory of natural selection was the final blow to Lamarckism.

English naturalist Alfred Russel Wallace (1823–1913) discovered natural selection independently of Darwin while in Indonesia and Malaysia from 1854 to 1862. Wallace sent Darwin a copy of his unpublished paper on natural selection in 1858. Darwin realized that he would have to act fast lest Wallace gain the credit for this discovery. Darwin enlisted Lyell and botanist Joseph Dalton Hooker (1817–1911) to present both his and Wallace's views on natural selection at the July 1858 meeting of the Linnean Society of

► CAPTAIN FITZROY, DARWIN, AND THE VOYAGE OF THE *BEAGLE*

From December 1831 until October 1836 Darwin sailed aboard a British Navy ship, HMS *Beagle*, on a scientific voyage to the Pacific. Original plans were that the *Beagle* should circumnavigate the world in two years, but Captain Robert Fitzroy's detailed survey of the west coast of South America extended the voyage to nearly five years. As the direct result of his extensive research on this voyage, especially in the Galapagos Islands in 1835, Darwin had his first inklings of the theory of natural selection in 1838 but kept it to himself until Wallace forced his hand. The irony is that Fitzroy was a fundamentalist Christian who later felt ashamed that many turned away from Christianity because of what Darwin did under his command.

—Eric v.d. Luft

An 1890 painting of the HMS *Beagle* in the Straits of Magellan. It was during the journey of the HMS *Beagle* that Darwin collected much of his scientific data that he later used to formulate the theory of evolution through natural selection. (Bettmann/Corbis)

London. Meanwhile Darwin began writing *On the Origin of Species*. Wallace did not mind Darwin preempting him, and they remained friends. Later Wallace advised Darwin to use the phrase “survival of the fittest,” coined by English philosopher Herbert Spencer (1820–1903), as a slogan to make natural selection easier to understand.

Probably the strongest contemporary scientific data supporting natural selection was gathered by English entomologist Henry Walter Bates (1825–1892). From 1848 to 1859 Bates studied insects in the Amazon River basin; Wallace accompanied him for the first four years of this expedition. Bates noticed that some weak, harmless, or edible insect species resembled strong, fierce, or inedible species. He surmised that the former group imitated the latter and that this was a natural development to protect the former. The defenseless insects that looked defenseless would be killed and eaten, but the defenseless ones that looked formidable would survive. As soon as Bates returned to England and learned about Darwinism, he began to correlate what he read in *On the Origin of Species* with what he had observed in Brazil. He published his results in 1862, coining the term “mimicry” to describe the aspect of natural selection that he had discovered.

German physician, zoologist, and comparative anatomist Ernst Heinrich Philipp August Haeckel (1834–1919) read *On the Origin of Species* in its first German translation in 1860. He immediately abandoned his medical career to devote himself to developing and promulgating a synthesis of Darwinian and Lamarckian evolutionary theories. Influenced by the romanticism of Johann Wolfgang von Goethe (1749–1832), the absolute idealism of Georg Wilhelm Friedrich Hegel (1770–1831), and the spirituality of German philosophy in general, Haeckel tried to understand the natural creativity behind evolution. Nevertheless, the explanations he provided for all evolutionary phenomena were grounded in physical and mechanical causes.

Swiss zoologist and cell biologist Albert von Kölliker (1817–1905) supported Darwinism but argued that evolution occurs in abrupt jumps, not gradually. Against Darwin's gradualism, Kölliker published his theory of catastrophism in 1864. It inspired many European scientists, particularly Dutch botanist Hugo de Vries (1848–1935), who claimed that sometimes evolution is so sudden that the next generation is a new species.

Part of Darwin's theory was pangenesis, the idea that particles from each cell in an individual collect in the gonads and transmit genetic

information to offspring. Darwin's first cousin English anthropologist Francis Galton (1822–1911) used statistics, biometrics, and environmental studies to bolster Darwinism in general and pangenesis in particular. Yet pangenesis acquired little support among scientists. Kölliker established in 1885 that each cell nucleus is the locus of inheritance. Thereafter the theory of pangenesis fell apart.

Mathematics

Between the mid-eighteenth century and the early twentieth century, advances were made in several branches of mathematics. One of the earliest fields to benefit from scrutiny was the study of probability. Before the 1770s mathematicians had confined probability theory to games of chance. Between 1774 and 1812 French mathematician, physicist, and astronomer Pierre Simon Laplace (1749–1827) published a series of papers that culminated in his *Analytical Theory of Probabilities* (1812) in which he expanded the study of probability to new areas. He used probability to estimate the longevity of France's population if smallpox disappeared, to determine the likelihood that the current sex ratio in France would continue for 100 years, and to calculate the magnitude of error in observation. An estimate of a tree's height, for example, will surely be imprecise, and Laplace used probability theory to gauge the size of error. French mathematician Simeon-Denis Poisson (1781–1840) took probability to questionable extremes in his *Recherches sur la probabilité des jugements en matières*

criminelles et matière civile (1837), using it, for example, to calculate the probability that a defendant would be acquitted or convicted of a crime. Poisson believed that he could make sound calculations without knowing the charge against the defendant or the evidence against him.

In addition to probability theory, mathematicians, in one of the significant developments of the era, united mathematics and science. This was not a new development. Mathematics and science had been closely related since the time of Archimedes, but since the late eighteenth century the closeness of this relationship became a defining feature of mathematics and science. In the early nineteenth century German mathematician Johann Gauss (1777–1855) regarded mathematics as the “Queen” of the sciences, and in 1881 American mathematician Benjamin Peirce classified mathematics as a science. Laplace made the greatest contribution to the fusion of mathematics and science, publishing in five volumes between 1799 and 1825 his *Celestial Mechanics*, a synthesis that describes in mathematical

➤ JOHANN CARL FRIEDRICH GAUSS

The son of a mill foreman, Johann Carl Friedrich Gauss was born April 30, 1777, in Braunschweig, Brunswick-Lüneburg. A prodigy, Gauss at age three corrected an error in his father's financial calculations. Given the task of adding all the numbers between 1 and 100, Gauss astonished his teacher by calculating the answer in seconds. Despite his precocity, his father wanted Gauss to be a mason. His mother, however, had more sympathy for Gauss's ambitions and encouraged him in his studies. The duke of Braunschweig, aware of Gauss's abilities, financed his education, first at Collegium Carolinum and then at the University of Göttingen. Gauss was originally interested in the study of languages, but interest in geometry drew him to mathematics. In 1799 he received a PhD from Göttingen. During his career Gauss worked in virtually every branch of mathematics. He was, according to one authority, the last generalist. After Gauss, the study of mathematics grew too large for any one person to know all the tenets of the discipline. Gauss died on February 23, 1855, in Göttingen, Hannover.

—Christopher Cumo

equations all that science knew about the motion of objects in the solar system. Laplace derived all motion in the solar system from Isaac Newton's fundamental equation of gravity.

Arguably the greatest contribution to mathematics during this era was the development of non-Euclidean geometry. Mathematicians had long questioned Euclid's fifth postulate, namely that given a line and a point, only one line can be drawn through the point and parallel to the line. This postulate was suspect because Euclid had not derived it from the other postulates. For centuries mathematicians had tried to vindicate Euclid by proving the postulate, but all attempts failed, leading a group of mathematicians to deny the postulate and to derive a new geometry. As early as 1792 Gauss had concluded that more than one line could be drawn through a point and parallel to a line. In Gauss's geometry the sum of the angles of a triangle was less than 180 degrees. These ideas were counterintuitive, and for fear of ridicule Gauss did not publish them. Instead, the Russian mathematician Nicolai Lobachevsky (1792–1856) became the first to publish a non-Euclidean geometry. In 1829 he attempted to prove, in violation of Euclid, that one could draw infinitely many lines through a point and parallel to a line. Like Gauss, Lobachevsky derived a geometry in which the sum of the angles of a triangle was less than 180 degrees. In 1832 Hungarian mathematician John Bolyai (1802–1860) derived a geometry similar to Lobachevsky's.

Perhaps German mathematician Bernhard Riemann published the most counterintuitive geometry. In 1868 he proposed that observation of space did not confirm the existence of parallel lines; therefore, Euclid's fifth postulate was invalid. In contrast to Gauss, Lobachevsky, and Bolyai, Riemann asserted that no parallels

may be drawn through a point. All lines must intersect, some of them at more than one point. Further, the sum of the angles of a triangle was greater than 180 degrees. While Riemann and others were creating a new geometry, German mathematician Moritz Pasch sought in the 1880s to define Euclid's postulates with a new rigor. For example, he refused to use the word "line" because no one had ever seen a line. Instead he preferred the phrase "line segment" because it corresponded with reality.

In addition to the greater fusion of mathematics and science, in the nineteenth and twentieth centuries mathematicians unified mathematics and logic. In *Investigation of the Laws of Thought on Which Are Founded the Mathematical Theories of Logic and Probabilities* (1854), British mathematician George Boole asserted that algebraic symbols need not stand for numbers. Rather, they could stand for words and even assertions. Boole's logic foreshadowed the logical structure of computer programs. In 1901 British mathematician and philosopher Bertrand Russell equated logic and mathematics. He also asserted that mathematics was derived from logic.

Between the late eighteenth and early twentieth centuries mathematics covered new terrain and developed new applications in probability, science, geometry, and logic. These centuries were a heady time to be a mathematician.

■ Introduction: Scientific and Technological Education

Scientific and technological education existed long before the Scientific Revolution. Ancient civilizations, beginning with those of ancient Mesopotamia, passed on practical knowledge and ideas about the natural world to

succeeding generations and in doing so employed forms of scientific and technical education. In Europe, medieval and Renaissance universities taught sciences based on the works of the ancient Greek philosopher Aristotle. For

mal instruction in modern, as opposed to ancient science, and technology began to appear in the mid-eighteenth century as Western universities and technical schools absorbed the expansion of knowledge created by the Scientific Revolution. The absorption was limited, however, as curricular changes were more dramatic at newly established technical schools than at centuries-old universities, still dedicated to a classical curriculum consisting of Latin, Greek, rhetoric, logic, mathematics, and philosophy. While eighteenth-century Harvard, Yale, Oxford, and Cambridge continued to teach vestiges of Aristotelian cosmology, technical schools in France and Germany introduced students to Newtonian physics.

Several developments from the late eighteenth century to the mid-nineteenth century inspired a demand for scientific and technological education. The new technologies themselves generated enthusiasm for practical studies. The British steam engine, the American cotton gin, the European rail system, the telegraph, and other new technologies reconfigured space and time in unprecedented ways. Popular interest in newly emerging technologies—along with their problems and promise—put pressure on educational institutions to respond to these developments. In addition, social changes connected with the Industrial Revolution encouraged formal scientific and technical training. With the decline of guilds and the gradual disappearance of training through apprenticeships, mechanics' institutes and institutes of technology were established in their place by laborers, educators, and manufacturers. Finally, European military demands contributed to the rise of polytechnic institutions. In 1808 Napoleon reorganized the French technical school system, in part to produce educated officers trained in military and civil engineering. Similar engineering instruction crossed the Atlantic with the establishment of academies and polytechnic institutions in North America, where as a result of western expansion, the demand for engineers who could survey land, develop turnpikes, chart canal ways, and build railroads increased dramatically in the nineteenth century.

Although newly formed independent institutes, academies, and technical schools supplied

much of the technical and scientific instruction in the 1800s, colleges and universities also responded by adding new courses and establishing new divisions or new academic units in engineering and science. Traditional institutions of higher learning increased course offerings in natural philosophy and natural history in the required and elective curriculum. When the expansion of course offerings crowded the undergraduate course of study, parallel degree programs were introduced to offer special training in scientific and technological education. Freed from the traditional requirements, students in these programs could draw from one or more areas in the sciences without taking courses that were part of the classical curriculum. Separate schools emerged partly out of dissatisfaction with the incoherence of selected courses or lack of prestige of parallel programs. Examples include Harvard's Lawrence Scientific School and Yale's Sheffield Scientific School, both of which were founded in 1847 and offered scientific and technical training.

From the mid-nineteenth century to the early 1900s, distinctions between technical schools and colleges and universities became blurred. Emphasis on Latin and Greek began to fade and was replaced with undergraduate and graduate instruction in the liberal arts, sciences, and practical studies. Traditional institutions of higher learning expanded offerings in technical studies, while advanced technical schools incorporated humanistic studies and foreign languages. In the case of the Massachusetts Institute of Technology (f. 1861), engineering and general science students received humanities and language instruction as part of their required studies.

Through colonization from the mid-nineteenth century onward, Western models of scientific and technical education spread to other parts of the world. British colonial higher education in Australia and India followed the pattern of the University of London and Ireland's Queen's University rather than Oxford or Cambridge. The curriculum consisted of traditional classical studies as well as scientific courses, including botany, chemistry, physical geography, zoology, and natural philosophy. In Australia, the model appeared at the University of Sydney (1850) and the University of Melbourne (1853). In India, the

University of Calcutta (1854) had as its focus the propagation of British culture and the training of future government officials, although it also offered degrees in medicine and civil engineering. In Africa, the work of missionaries and British policy contributed to the development of industrial training and technological studies. Technical institutes or departments at established schools were founded in Freetown (1896), Accra (1898), and Lagos (1899). Emphasis in these programs was on the practical work in such areas as manufacturing processes and botany.

Asian and Latin American higher learning followed a less direct process of importation of scientific and technical education. Western mathematics in China appeared with the arrival of Jesuit missionaries in the mid-seventeenth century, but formal systems of technical instruction first were established with the Fuzhou Shipyard (1866), followed by Nanyang College (1896) in Shanghai, which offered physics and other basic sciences. Latin American institutions of higher education, some of the oldest in the Americas, focused on the preparation of elites for political and legal administration until the late nineteenth century and the early twentieth century. At the turn of the twentieth century, the founding of mining and engineering institutions appeared throughout Central and South America.

—A. J. Angulo

Technical Schools

Technical schools first began to appear in mid-eighteenth-century Europe. They differed from previous forms of technical education in that they were independent institutions of higher learning that offered formal, systematic

instruction in practical and scientific studies. These institutions were established and received greatest support in regions that sought to expand military capacities, were experiencing rapid industrialization, and had existing scientific and mathematical expertise. The worldwide development of technical schools can be traced along three periods: origins (1750–1820), consolidation (1820–1870), and expansion (1870–1914).

Technical schools originated in Paris, where educational institutions such as the École des Ponts et Chaussées (1747), École Polytechnique (1794), and École Central des arts and manufactures (1829) provided models for technical school development elsewhere. The École des Ponts et Chaussées offered the first organized program of civil engineering in the modern world. Courses in its three-year curriculum included mathematics, physics, chemistry, architecture, and field assignments for the application of scientific knowledge. This and later French institutions formed a coordinated system of technical education that prepared engineers for military, civilian, mining, mechanical, and other needs. Institutions influenced by the Parisian schools included the United States Military Academy at West Point (1802); Rensselaer Polytechnic Institute (1824) in Troy, New York; the Massachusetts Institute of Technology (1861) in Boston; and such Germanic institutions as Berlin's Vereinigte Artillerie und Ingenieurschule (1788), Bauakademie (1799), and Karlsruhe's Polytechnische Hochschulen (1825). Early though less influential Russian technical instruction can be traced back to Peter the Great's founding of the Moscow School of Mathematics and Navigation.

In Western societies the consolidation of technical schools gave these new institutions a

► MORALITY AND TECHNICAL STUDIES

During the early to mid-nineteenth century Great Britain underwent a period of transformative industrialization, colonial expansion, and technological innovation. Despite similar forces that contributed to the establishment of technical schools elsewhere, the British fell behind European neighbors in organizing formal technical studies. Much of the nation's applied and practical instruction was left to Mechan-

ics' Institutes that aimed physics, chemistry, mathematics, earth and life sciences, phrenology, and drawing at the working classes. Leaders of the Mechanic Institute movement believed that scientific education for the working class would serve the purposes of moral improvement, curbing drunkenness, debauchery, and promiscuity.

—A. J. Angulo

secure footing within the higher education landscape. This occurred within a confluence of social, political, and cultural forces. Social forces fueling consolidation centered primarily on the rise of industry and the decline of the apprenticeship system, popular interest in scientific and technological advances, and the organization of the scientific professions. Independent technical institutions arose as a result of the lack of attention to science and technological studies in traditional higher education. Political forces also provided the impetus for the founding and expansion of technical schools. In the United States, for example, the Land Grant Act of 1862 strengthened the technical school movement by funding institutions offering agricultural and mechanical instruction through the sale of lands on the western frontier. There was a substantial increase in the number of American technical schools (from 6 to 70) between 1862 and 1870. Despite the increase in schools established and their funding, a divide between shop culture and school culture persisted. Shop culture, composed of those who learned on the job, resisted the influence of school culture represented by those who received formalized instruction in practical, engineering, scientific, and mathematical studies.

By the start of the expansionist period, technical school culture had begun to professionalize and spread its values around the world. Australia's Industrial and Technological Museum led the nation in offering technical studies in 1870. Japan's Imperial College of Technology (later Tokyo University) opened in 1872 as a Western-styled technical school under the direction of Scottish engineer Henry Dyer (1848–1918). Calcutta's Indian Association for the Cultivation of Science (1876) assisted regional colleges and universities in the expansion of technical studies. The expansion continued during the late nineteenth and early twentieth centuries, from the Middle East (i.e., Iran's secular Dar Al-Funun) to Latin America (i.e., Colombia's School of Engineering of the National University). The formation of technical schools was impeded in regions with lesser-developed centralized governments, militaries, industries, literacy rates, and scientific and mathematical communities. In such regions,

Painting of the Bauakademie, by Eduard Gaertner, 1868. The building, constructed in Berlin between 1832 and 1836, housed the Royal Technical High School, the forerunner of the Technical University, founded in 1879. (Preussischer Kulturbesitz/Art Resource, NY)

students interested in scientific and practical studies sought instruction abroad.

Engineers as a New Professional Group

The roots of engineering as an organized profession lie in eighteenth-century Europe and were dominated by two contrasting models. In continental Europe, the engineer was the recipient of professional training at a school, often

➤ RICHARD TREVITHICK IN PERU

The career of Cornish engineer Richard Trevithick (1771–1833) in Peru indicates both the opportunities and the perils that foreign travel could offer an engineer. Trevithick was a self-taught mining engineer who worked on steam engines and locomotives, devising many innovations but never earning much money. In 1816 he set out for Lima to supervise the installation and operation of engines he had designed for Peruvian silver mines. Trevithick was initially welcomed, but his South American enterprises failed because of rivalries with local businessmen and disruptions caused by the Latin American wars of independence from Spain. In 1827 Trevithick, broke, had a rare stroke of luck in encountering a fellow British locomotive engineer, Robert Stephenson, in Cartagena. Stephenson lent Trevithick 50 pounds to return to England. Although Trevithick continued to register patents, his English career never recovered from his absence, and he died a poor man.

—William E. Burns

affiliated with the government, while British engineers trained through a system of informal apprenticeship.

France, the world's leader in engineering education in the eighteenth century, treated the engineer as a servant of the state. As in other countries, the engineering profession was closely allied with the military, a bond that grew even tighter after the French Revolution with the founding of the Polytechnic School in 1794. (The term “engineer” was originally used in the military context to refer to management of sieges and the construction of fortresses.) The French also excelled in civilian engineering, particularly after the founding of the School of Bridges and Roads in 1747. Other continental countries followed the French model, with the founding of institutions modeled on the Polytechnic in Berlin in 1799, Prague in 1805, and Vienna in 1815. The U.S. military academy at West Point also drew heavily from the polytechnic model and was originally under the direction of the Army Corps of Engineers. Mining was particularly important in training German engineers, with numerous mining academies scattered through the German lands.

British engineers were more likely to work for private industry than for the government, although Britain maintained a faculty to train military engineers at the Royal Military Academy at Woolwich. Scotland, with its excellent educational system and a poverty that rendered it unable to support all of its own population, became particularly famous as a nursery of engineers, a reputation that it would keep into the twentieth century. The British civil engineer was not a state functionary like his counterpart in France but instead was a contractor who worked for different clients, the state being only one among them. The United States mostly followed the British model. The U.S. institutions of higher education outside West Point taught little engineering until the founding of the Massachusetts Institute of Technology in 1865 and the establishment of the land-grant colleges in the late nineteenth century. Although British and American engineers lacked the French experience of passing through training together, they had an increasingly strong sense of themselves as part of a profession, with the founding of the Institution of Civil Engineers in Britain in 1818. The American Society of Civil Engineers, the oldest engineering society in the United States, was founded in 1852.

The Industrial Revolution and the railway age increased the importance of engineers throughout the world and also opened many job opportunities beyond the military. Engineers spread over the world with the growth of industry and imperialism, building bridges, establishing factories, and building and maintaining engines for many uses. The growth of entire new areas of technology, such as electrical power and the chemical industry, also made engineering more intellectually demanding and the teaching of engineering a greater priority.

By the late nineteenth century German engineering had become a world leader, with the foundation of the system of technical high schools that were the envy of many other countries along with the excellent German universities. Much of the German rise to industrial leadership rested on the skills of its engineers. The British were increasingly aware of the poor quality of their technical education infrastructure, but despite frequent and increasingly

desperate calls for reform to keep up with the Germans, little was actually done.

Throughout the industrial world engineers were admired and in some cases, notably with British engineer Isambard Kingdom Brunel and the self-taught American Thomas Edison, even became celebrities. Engineers were set forth as role models for boys, as in the works of the Victorian biographer Samuel Smiles. Engineering was increasingly seen as the key to technological and economic progress, with the creation of engineering programs and institutions in countries wishing to catch up with the developed world of Europe and the United States. This process went back to the founding of the Naval Engineers School in Ottoman Turkey in 1773. The British established the Thomason College of Civil Engineering (later the Indian Institute of Technology) in India in 1847, and Zionists founded the Techicum (later the Israel Institute of Technology) in Haifa in 1912. The Tokyo College of Technology was founded in 1890. The engineer became a symbol of modernity and a new cultural hero, often contrasted with traditional religious leadership.

The engineering profession was highly masculine. As women attempted to batter down the barriers that kept them out of other professions such as medicine and law, there was relatively little pressure to make engineering less male-dominated.

Scientific and Technological Education in Meiji Japan

During the Meiji period (1868–1912), Japan experienced an unprecedented emphasis on science and technology in education led by former Tokugawa domains that had already started developing new technology in the nineteenth

century and also by the new oligarchy under Emperor Meiji (1852–1912). Japan's Ministry of Education was created in 1871, and in 1872 the Fundamental Code of Education was promulgated, stating that universal primary education should be extended to all citizens. Previously in the Tokugawa period (1600–1868), attending schools had been a privilege for children of the samurai class only. The term that would become the word for “science” in Japanese, *kagaku*, was first understood to mean “classified learning,” which referred to a number of subjects, not just science exclusively. The first use of the term “*kagaku*” in an essay, in 1871, has been attributed to the statesman Inoue Kowashi, who later drafted the Proposals on Education for Prime Minister Ito Hirobumi, who in turn presented these ideas to the emperor.

Interest in science and technology in Japan preceded the Meiji era. Although relations with foreign powers during the Tokugawa period were strictly regulated, the port of Nagasaki in Kyushu served as a conduit for knowledge from the outside world, including new ideas regarding astronomy, cartography, medicine, and military

➤ KITASATO SHIBASABURO

Kitasato Shibasaburo (1852–1931) was the leading Japanese bacteriologist during the Meiji period. On a foreign study program at the Koch Institute in Berlin, Germany, he succeeded in identifying the bacterium that caused tetanus in 1889. In 1894 at the urging of Japan's Bureau of Public Health, Kitasato went to Hong Kong during a plague epidemic. His work there, in tandem with Aoyama Tanemichi, led to the isolation of the bubonic plague bacillus. This achievement, announced in the medical journal *The Lancet*, brought Kitasato to international attention and highlighted the scientific progress of Japan. His own career evidenced the tension between individual scientific endeavors and the need for institutional loyalty. Kitasato's career was influenced by a variety of educational institutions, mentors, and colleagues, but he preferred placing faith in the technical expertise of trusted friends rather than adhering to the unswerving loyalty that many Meiji governmental organizations and schools demanded.

—Christopher Dewell

science from the Dutch and innovations in agriculture, mathematics, and traditional medicine from China. In 1811 the Tokugawa government founded the Bansho Wage Goyo, or Office for Translating Barbarian Books, for the express purpose of bringing Western learning to the Japanese. With few exceptions, however, such as Ogata Koan's private academy the Tekitekisai Juku, established in Osaka in 1838, there was no systematic approach to the study of science.

Tokugawa domains like Satsuma and Choshu, geographically removed from the shogunate's capital at Edo (present-day Tokyo) and nearer to China, were influenced by the encroachment of Western imperialists, particularly after the effectiveness of European weaponry was demonstrated in the First Opium War (1839–1842) between China and Britain. By the 1860s they both were acquiring Western military technology. These two domains later joined forces in 1867 to fight for the overthrow of the Tokugawa government, which they held accountable for failing to resist growing Western imperialism in Japan.

As the Meiji government embarked on its campaign to educate all Japanese children, science and technology were emphasized. At the equivalent of primary school, fully one-third of the curriculum was given over to mathematics and science teaching in the 1870s and 1880s, and in higher grades the focus expanded to two-thirds. Among Tokyo University graduates in the 1880s, 85 percent had concentrations in a scientific field, and a large proportion of these students came from samurai family backgrounds. These graduates fueled the drive for industrialization initiated by the Meiji government, as they

helped develop railway, mining, and factory operations as technicians and engineers. To aid in acquiring new technical knowledge, foreign experts from China and Western countries had been hired in the final years of the Tokugawa period, a practice that continued under the Meiji government. Now, however, with newly minted Japanese university graduates in the sciences, there was a steady supply of indigenous manpower to take the place of these foreign technicians once they returned home.

While innovations in the Tokugawa period had provided a foundation for many of the changes that took place during the Meiji era, the acquisition of science and technology became state-centered priorities under the Meiji government. This new emphasis also contributed to a sense that these formerly separate geographic regions were increasingly linked by shared interests in promoting the economy and the state. This focus on science and technology was integral in producing the first industrialized nation in Asia.

■ Introduction: Medicine

For most of history the human effort to prevent disease, cure the sick, and mend the injured is a story of flawed theories and depressingly meager results. This changed in the nineteenth century when, it is safe to say, more progress was made in the art of healing and the science of disease prevention than in all of human history to that point. The advance of

medicine was a uniquely European accomplishment, and Europeans and people of European descent were its first beneficiaries. Ultimately, however, it had worldwide consequences, not just for millions of individuals but also for the human species as a whole, whose dramatic increase in numbers in the twentieth century rested on the foundations of increased agricul-

tural production, higher incomes, and better medicine.

Medicine and the related discipline of anatomy had been intensively studied in Europe since the Middle Ages. Most medieval universities had faculties of medicine where students studied in Latin translation the works of Galen (129–199/217 CE) on anatomy, Hippocrates (ca. 460–370 BCE) on medical practice and diagnosis, and their Islamic commentators. During the Renaissance and the early modern period, dissection of human cadavers became a part of the study of anatomy at a number of universities; William Harvey (1578–1657) accurately described the circulation of blood; and a number of new procedures, including the use of forceps in childbirth, were introduced. But no real progress was made in treating the sick. In this regard the poor, who relied on prayer and folk remedies, were probably better off than the well-to-do, who shortened their lives by paying academically trained physicians prescribe purgings, bleedings, cold-water baths, treatments with magnets, and a variety of dubious pills, powders, and elixirs. Significantly, two medical advances before the nineteenth century—the use of cinchona bark to treat malaria and the practice of variolation to prevent smallpox—were both imports, the former from South America and the latter from the Ottoman empire, where the woman who first promoted the practice in Europe, Lady Mary Montagu (1689–1762), observed it.

Modern medicine was a creation of the nineteenth century. It began in the hospitals of Paris, recently removed from the control of the Catholic Church during the French Revolution, where in the 1790s and early 1800s thousands of aspiring physicians were taught to put away their books and look for the causes of disease in the bodies of the sick and recently dead. Autopsies became the focus of research and teaching, resulting in new understanding of the pathology of heart disease, strokes, cancer, tuberculosis, and other maladies. This Parisian drive to find the internal causes of disease in 1816 gave birth to Jean Nicholas Corvisart's invention of the stethoscope, an instrument that gave physicians the ability to “see” into the body by hearing the sounds of breathing, the heartbeat, and the workings of intestines. The French model of

systematic and scientific hospital-based medical training had many imitators. By midcentury it had spread to Vienna, Edinburgh, Dublin, London, and other European cities.

While the sick bed and morgue was the center of the pathological research of the Parisians, in Germany the laboratory took center stage. Benefiting from improvements in the microscope and the development of a host of new instruments and techniques for weighing, measuring, and testing, German university laboratories made important discoveries in microscopic anatomy, cell structure, the chemistry of digestion, and metabolism. Laboratory-based chemists also made strides. During the first half of the nineteenth century they extracted the active ingredient from many plant substances long used in medical practice and by doing so made it possible to regulate the purity and dosage of medications such as morphine, codeine, quinine, colchicine (for the treatment of gout), and others.

At the end of the century the laboratory gave birth to the most important single development in the history of nineteenth-century medicine: the new discipline of bacteriology. The theory that diseases were caused by tiny invasive beings was not new, but until the late nineteenth century this theory made little progress against the competing theory that disease was caused by miasma, a noxious form of “bad air” filled with small particles or vapor from decomposing matter. This changed as a result of the work of two men, Louis Pasteur (1822–1895) and Robert Koch (1843–1910). Pasteur set forth his ideas in a groundbreaking speech before the French Academy of Medicine in 1878 in which he spelled out his conviction that microorganisms were responsible for putrefaction, fermentation, and disease; that only specific organisms caused specific diseases; and that once the disease-causing microorganism was known, vaccines to prevent the disease would be possible. His work resulted in vaccines for anthrax, chicken cholera, and rabies, and research carried out at the Pasteur Institute, founded by Pasteur in 1887, led to the discovery of the bacillus that causes plague and contributed to the development of an antitoxin for treating diphtheria. Koch made equally important contributions. He and his students developed new bacteriological techniques, including

the use of agar-agar, an extract from Japanese seaweed, as a culture medium; they also discovered the bacilli that cause tuberculosis and cholera. Not all bacteriological discoveries led to cures or effective vaccines. Koch's much-heralded cure for tuberculosis, "tuberculin," proved to be worthless, and the causes of scarlet fever baffled researchers until after World War I. Nonetheless, the work of Pasteur, Koch, and others fundamentally changed how sickness was understood and treated.

During the nineteenth century, many other significant changes occurred. Once the connection between urban filth and disease epidemics was clearly established in the 1830s and 1840s, governments took on new responsibilities for public health through the construction of sewers and clean water systems. In 1847 the Hungarian physician Ignaz Semmelwies discovered that the simple act of having midwives and physicians wash their hands in a chlorinated lime solution caused a dramatic fall in the incidence of childbed fever, a major cause of death among new mothers. Surgery was transformed by the development of anesthetics and the gradual acceptance of antiseptic practices in the operating room. In addition to the stethoscope, new devices were invented to measure patients' blood pressure, temperature, respiration, and pulse. Chemical tests were developed to diagnose diabetes and diseases of the kidneys. Hospitals, viewed in the eighteenth century as places where the sick and poor went to die, were transformed into respected medical institutions for teaching, research, surgery, and the treatment of the sick. In this transformation, the elevation of nursing to a respected skilled profession for women played a key role. The founding of specialty hospitals for the treatment of children or specific diseases of the skin, eyes, colon, bones, and nervous system was symptomatic of the development of specialization within the medical profession itself.

These revolutionary changes were not completely limited to Europe and areas of European settlement. Medical missionaries introduced some practices of modern medical treatment to their patients in European colonies and the Middle East; British army doctors trained Indians to serve in the Indian Medical Service; European academics helped establish the first

Western-style medical schools in Japan and the Middle East; and European bacteriologists and physicians made breakthroughs in the understanding and treatment of tropical diseases such as malaria, yellow fever, and African sleeping sickness. Nonetheless, what was true in terms of wealth, technology, education, and military power also applies to medicine and health: as a result of nineteenth-century developments, the gap between the West and the rest of the world became immeasurably wider.

—James H. Overfield

Colonialism and Public Health

As Europeans became the colonial rulers of much of Africa and southern Asia in the nineteenth century, they naturally became concerned with matters of health and disease in their colonies. In fact, the field of tropical medicine was created largely as a response to European exposure to tropical diseases in Africa and Asia. The legacy of colonial medicine had both positive and negative aspects. While colonization often disrupted and devalued traditional ways of life and reinforced the power and preeminence of the colonial rulers, it also introduced scientific medicine and public health practices to areas earlier than might otherwise have been the case.

The main purpose of colonial health services was to protect primarily the health of European soldiers and administrators, followed by that of European settlers and their families, and finally that of the native population whose ill health could limit their productivity and spread disease to the Europeans. Health services in the colonies were generally concentrated in areas where Europeans lived, so native peoples living in cities were much more likely than those living in the countryside to benefit from medical and public health services. Colonial health services were also typically segregated by race, with Europeans, for example, receiving better rooms and care in hospitals.

Public health measures such as vaccinations, quarantines, and port controls were instituted in some colonies. However, the sanitation revolution taking place in nineteenth-century America and Europe, which improved the health of city dwellers through provision of municipal water,

the construction of sewage systems, and other reforms, came to the colonies much later. Living conditions for natives in colonial cities often remained appalling well into the twentieth century, and conditions in colonial health institutions for the native population were often remarkably bad. For instance, the annual death rate in the lunatic asylum of Singapore in 1900 was reported to be 683 per 1,000.

Some aspects of colonial rule certainly worsened the health of the native population. For instance, the construction of needed infrastructure to provide clean water and treat sewage in cities that were administrative or commercial centers rarely kept pace with the rapid population growth. New diseases such as measles and influenza were introduced to populations without immunity, and venereal diseases were spread through the creation of a sexual marketplace. Sometimes the health of native peoples suffered when they were forced to move to areas they had previously avoided because diseases such as malaria were known to be endemic there. The imposition of cash-crop agriculture often forced native peoples to change their diets to less nutritious foods. In the Philippines, outbreaks of beriberi, a disease caused by a vitamin B deficiency, resulted from the U.S. introduction of machine-milled white rice in the early 1900s.

Colonial rulers gradually became aware, however, that the health of native people was their concern because infectious diseases could spread from natives to Europeans and also because natives who were constantly ill were less-productive workers. Additionally, it was part of the colonial ideology to bring the benefits of Western medicine to so-called backward natives, which also provided an extension of government control into people's lives. By the early twentieth century, many colonial powers began to introduce public health programs intended to benefit the native peoples, including the introduction of systems for the sanitary disposal of sewage and for the provision of clean water.

➤ YELLOW FEVER IN WEST AFRICA

Sir Rupert Boyce, an English physician and founder of the Liverpool Yellow Fever Bureau, noted the connection between economic development in West Africa and the spread of yellow fever by mosquitoes in an article written in 1911:

"It [the mosquito] is not a swamp, gutter, or puddle breeder; it is essentially the mosquito which breeds in *all receptacles* which happen to contain clean water. . . . Hence it comes to be the mosquito of all discarded tins [cans], bottles, &c., &c. Hence it is most abundant where there are traders, and is least abundant in the interior, where there is less trade. . . . Increased trade and commercial activity provide an increase of odd water-containers of all kinds, and therefore . . . a greater liability of Yellow Fever."

—Sarah Boslaugh

Modern Surgery

Surgery is the active and deliberate physical intervention into the body for the purpose of curing disease or healing injury. Surgical operations cause bleeding and pain and put the patient at risk for infection and death. Therefore, complex effective surgery was not possible until three conditions were met: control of pain, prevention of infection, and control of bleeding. All three of these problems were solved in the last 60 years of the nineteenth century.

The single most important event in the history of medicine was Ether Day, the successful introduction of sulfuric ether as general anesthesia at Massachusetts General Hospital on October 16, 1846. Nearly two years earlier,

An illustration showing the first administration of ether during surgery in 1846. The scene at Massachusetts General Hospital shows William T. G. Morton, at left, administering anesthesia to Gilbert Abbot while John Collins Warren operates. (Bettmann/Corbis)

on January 31, 1845, at Harvard Medical School, dentist Horace Wells (1815–1848) and surgeon John Collins Warren (1778–1856) attempted to anesthetize a dental surgery patient with nitrous oxide but failed, causing the patient much suffering. Wells despaired and committed suicide, but Warren persisted.

One of Wells's dental students, William Thomas Green Morton (1819–1868), collaborated with physician and chemist Charles Thomas Jackson (1805–1880) to produce *Letheon*, a mixture of sulfuric ether and several inert compounds included to mask ether's unique odor. Morton offered *Letheon* to Warren, who agreed to test it. Warren had a patient named Gilbert Abbott who needed to have a vascular abnormality removed from his neck. After Warren prepared the patient in the operating theater on the top floor of the Bulfinch Building at Massachusetts General Hospital, Morton used a glass inhaler to anesthetize Abbott with *Letheon*. Warren then made a deep 3-inch incision and performed the surgery without complication. Abbott did not fall completely asleep. He remained groggy throughout the procedure but felt no pain. He later said that he felt only

slight discomfort in his neck, as if he were being scratched. This was Ether Day.

Over the next few weeks Morton served as anesthesiologist for several other Boston surgeons and achieved similar triumphs. A surgeon who was present at the first four anesthetic operations, Henry Jacob Bigelow (1818–1890), published "Insensibility during Surgical Operations Produced by Inhalation" in the *Boston Medical and Surgical Journal* on November 18, 1846. This was the first report of successful surgical anesthesia. On March 30, 1842, four and a half years before Ether Day, Crawford Williamson Long (1815–1878), a country doctor in Jefferson, Georgia, first used sulfuric ether for a minor surgical procedure. Because Long did not publish his results until 1849 and because the Boston surgeons published their results immediately in 1846, Morton and Warren get the credit for revolutionizing surgery.

The second condition for modern surgery, control of infection, has two aspects: antisepsis (the killing of microorganisms) and asepsis (the maintenance of a sterile environment). Hungarian obstetrician Ignaz Philipp Semmelweis (1818–1865) discovered antisepsis when he noticed in 1847 that new mothers had better survival rates from puerperal fever when obstetricians washed their hands between patients. American physician Oliver Wendell Holmes (1809–1894) learned of these results in 1855 and immediately began promoting Semmelweis's campaign for hospital cleanliness. American gynecologist James Marion Sims (1813–1883) began using clean silver sutures in the mid-1850s. English surgeon Joseph Lister (1827–1912) first used carbolic acid spray to disinfect his operating room on August 12, 1865, and published his results in 1867. Around the same time French biochemist Louis Pasteur (1822–1895) began advocating heat sterilization of surgical instruments.

Many prominent doctors, notably American surgeon Samuel David Gross (1805–1884), were skeptical of Semmelweis, Holmes, Sims, Lister, and Pasteur. That generation of surgeons had to die out before antisepsis would be accepted. Antiseptic methods became firmly established as surgical routine only after American surgeon William Stewart Halsted (1852–1922) began wearing rubber gloves in the operating room

at Johns Hopkins Hospital in the early 1890s. Following Halsted's lead, research teams in the twentieth century learned how to create asepsis for the duration of a surgical procedure.

The final condition for being able to perform long and complex surgical procedures was achieved in the 1890s when American surgeon George Washington Crile (1864–1943) gradually discovered how to manage bleeding to prevent blood loss and surgical shock. He published his methods in three books: *An Experimental Research into Surgical Shock* (1899), *Blood-Pressure in Surgery* (1903), and *Hemorrhage and Transfusion* (1909).

The Rise of Pathological Anatomy

Pathological anatomy is the scientific postmortem comparison of diseased or deformed tissue with healthy or normal tissue in order to learn the structural differences between them. The practical, clinical advantage is that the knowledge gained from this study enables physicians to correlate what they observe in living patients with what they have seen in the anatomical laboratory, thus enabling them to diagnose more accurately and treat more effectively.

The first medical scientist to correlate specific lesions with specific diseases, and thus the earliest progenitor of pathological anatomy, was Giovanni Battista Morgagni (1682–1771), professor of anatomy at the University of Padua. As

ANESTHESIA REACHES ENGLAND

Before anesthesia, patients tried opium, marijuana, alcohol, ice, hypnotism or mesmerism, prayer, chanting, acupressure, and "biting the bullet" as pain killers. None were effective, so the best surgeons were the fastest. The less time they spent cutting, the less the patient suffered. The world's most renowned surgeon in the era just before Ether Day was Sir Robert Liston (1794–1847), a Scotsman who could do a full amputation in about six seconds. Liston decided to try ether on December 21, 1846, at University College Hospital in London to perform the first anesthetic operation outside the United States. He worked slower than usual to amputate Frederick Churchill's leg at the thigh. The operation took 28 seconds. When Churchill awoke and asked Liston when he was going to begin, the surgeon was so pleased that he is reported to have exclaimed, "This Yankee dodge, gentlemen, beats mesmerism hollow."

—Eric v.d. Luft

the founder of the modern science of pathology and author of *De sedibus et causis morborum per anatomen indagatis* (*On the Origins and Causes of Disease as Investigated through Anatomy*), Morgagni was among the first to recognize that the treatment and cure of any disease depends in large measure on an understanding of its causes.

Most of the pioneer work in pathological anatomy was done in London or Paris. The most important results in England were achieved by Scots. Matthew Baillie (1761–1823), Scottish-born physician to King George III, produced several major texts on morbid or diseased anatomy and also produced the first good pathological atlas. Scottish surgeon, anatomist, and artist Sir Charles Bell (1774–1842) explored the nervous and circulatory systems and accurately described and illustrated many pathological conditions, including Bell's palsy (unilateral facial paralysis). In 1838 another Scot, Robert Carswell (1793–1857), published his monumental atlas *Pathological Anatomy: Illustrations of the Elementary Forms of Disease*, which contained the first description of multiple sclerosis.

THE INVENTION OF THE STETHOSCOPE

Laënnec invented the stethoscope on the spur of the moment, almost by accident. Not all physicians in his time chose to listen to the heart and lungs, but those who did, including Laënnec, would put an ear directly on the chest of the patient. One day he was frustrated using this method to try to hear the heart of an unusually obese and large-breasted woman. Instinctively he rolled a few sheets of paper into a tight cylinder and put it between her chest and his ear. He then heard the heart clearly. This was the first stethoscope. He named the instrument from two Greek words that suggest “seeing into the chest.”

—Eric v.d. Luft

René Laënnec prepares to use his stethoscope on a patient, from a painting by Théobald Chartran, 1819. (National Library of Medicine)

Viennese physician Leopold Auenbrugger (1722–1809) developed useful techniques to hear chest sounds and diagnose chest diseases in the 1750s and 1760s, but little improvement in medical practice resulted from this discovery until Napoleon Bonaparte’s physician, Baron Jean-Nicolas Corvisart des Marets (1755–1821), translated Auenbrugger’s 1761 book from Latin into French in 1808. Corvisart and his students compared Auenbrugger’s descriptions of living sounds with what they found in cadavers. Among Corvisart’s students at the Collège de France and l’Hôpital de la Charité in Paris was René-Théophile-Hyacinthe Laënnec (1781–1826), who invented the stethoscope in 1816. In addition to being a diagnostic tool, the stethoscope enabled a wider variety and a deeper subtlety of sounds that were heard inside the patient to be later correlated with physical findings at the patient’s autopsy.

The research of French comparative anatomist Marie François Xavier Bichat (1771–1802) shifted the focus of pathology from the organ to the tissue. Bichat identified and described 21 different kinds of living tissue, thus founding histology, the systematic study of tissue structures. Moreover, by examining these tissues in both their healthy and diseased states, he founded the clinical science of histopathology, the study of diseased tissues, 30 years before good microscopes became available.

Baron Guillaume Dupuytren (1777–1835), a French surgeon, established pathological anatomy as both the confirmation of successful surgical procedures and the guide for future procedures. He was so convinced of its value in his surgical practice that he bequeathed 200,000 francs to the University of Paris to create a professorship of pathological anatomy. His student Jean Cruveilhier (1791–1874) was the first

to hold this chair. Cruveilhier's gigantic two-volume atlas *Anatomie pathologique du corps humain* (*Pathological Anatomy of the Human Body*), which appeared gradually in 40 fascicles from 1829 to 1842, remained state of the art for 50 years until cellular pathologists were able to correct his errors in the late nineteenth century with advanced microscopes.

The most prominent clinician to break new ground by using pathological anatomy in his medical practice was another Frenchman, Pierre Charles Alexandre Louis (1787–1872), whose studies of tuberculosis, other respiratory diseases, and typhoid contributed not only to the understanding of these diseases but also to epidemiology and preventive medicine.

The Germ Theory of Disease

The germ theory of disease is that microorganisms cause some diseases and that certain microorganisms are specific to certain diseases. Until German pathologist Robert Koch (1843–1910) developed his ideas of infectious diseases in the late nineteenth century, physicians could only guess about what caused them and what might be done to prevent them. Koch's work replaced these conjectures with science. He won the 1905 Nobel Prize in Medicine for discovering the bacillus that causes tuberculosis.

The science of microbiology, the study of microscopic life, arose in the seventeenth century through the work of Dutch lens grinder Anton van Leeuwenhoek (1632–1723) and English general scientist Robert Hooke (1635–1703). Microbiology did not have any pathological implications until the middle of the nineteenth century. Four events led scientists to suspect that microorganisms might have some

connection with disease. First, in 1847, Hungarian obstetrician Ignaz Philipp Semmelweis (1818–1865) observed that new mothers got sick less often when their doctors had clean hands. Second, in 1859, French biochemist Louis Pasteur (1822–1895) disproved spontaneous generation, the traditional idea that microscopic life and even animals as large as flies, mice, and frogs arise spontaneously from non-living matter. Third, in 1862, Pasteur discovered that heating foodstuffs below the boiling point, a process later called pasteurization, prevents fermentation and spoilage. Fourth, in 1865, English surgeon Joseph Lister (1827–1912) reduced

Illustration of bacteria from Robert Koch's *Investigations into the Etiology of Traumatic Infective Diseases*, 1880. Koch was a physician who received a Nobel Prize in 1905 for identifying the bacillus that causes tuberculosis. (Library of Congress)

THE BEGINNINGS OF MODERN EPIDEMIOLOGY

Medical statistics are essential in the fight against infectious diseases. This fact was not generally recognized until the nineteenth century but became important evidence toward accepting germ theory. Among the pioneers in the practical application of medical statistics was English physician John Snow (1813–1858). In August and September 1854 a cholera epidemic hit London. Snow noticed that 127 people died in three days within a small radius of a well on Broad Street. He did not know what caused cholera, but on September 8 he had the well disabled by removing the pump handle, thus dramatically reducing cholera deaths in that area of London. The incident of the Broad Street pump marks the beginning of modern epidemiology.

—Eric v.d. Luft

the incidence of infection among his patients by spraying carbolic acid in his operating room.

As Koch began to suspect that bacteria caused disease, he formulated four principles to guide his research. Known as Koch's Postulates, these principles define a rigorous scientific method to correlate each disease with its particular microorganism and remain important for all epidemiological investigations. First, the suspect microorganism must be present whenever the disease occurs. Second, the microorganism must be isolated from the diseased host and grown in a sterile culture. Third, the pure culture of the microorganism must create the same disease when inoculated into a healthy, susceptible host. Fourth, the microorganism must be isolated from the second host and demonstrated to be identical with that from the first host. Koch published his postulates in 1882 in the same paper that announced his discovery of the tuberculosis bacillus.

Norwegian microbiologist Gerhard Hansen (1841–1912) published his discovery of the leprosy bacillus in 1874. This was the earliest definite correlation of a microorganism with a disease. Dozens of similar discoveries soon followed. Bacilli were identified for anthrax by Koch in 1876, gonorrhea by German physician Albert Neisser (1855–1916) in 1879, typhoid

fever by German physician Karl Joseph Eberth (1835–1926) in 1880, diphtheria by German pathologist Theodor Klebs (1834–1913) in 1883, cholera by Koch in 1884, tetanus by German physician Arthur Nicolaier (1862–1942) in 1884, meningitis by Austrian pathologist Anton Weichselbaum (1845–1920) in 1887, bubonic plague by Swiss bacteriologist Alexandre Yersin (1863–1943) in 1894, and dysentery by Japanese bacteriologist Kiyoshi Shiga (1871–1957) in 1898.

More general discoveries were staphylococcus by Scottish surgeon Alexander Ogston (1844–1929) in 1881, streptococcus by German American surgeon Friedrich Fehleisen (1854–1924) in 1882, and salmonella by American veterinarian Daniel Elmer Salmon (1850–1914) in 1886. Scientists discovered so many infectious bacteria in the last quarter of the nineteenth century that this era is known as the Golden Age of Bacteriology.

Most of the first pathogenic, or disease-causing, microorganisms to be discovered were bacteria, but some protozoans, parasites, and viruses were also discovered to be infectious. In 1880 French physician Charles Louis Alphonse Laveran (1845–1922) discovered plasmodium, the unicellular parasite that causes malaria. Russian botanist Dmitri Iwanowski (1864–1920) founded the science of virology in 1892 by announcing that he had discovered an extremely tiny microorganism that could infect tobacco plants but did not behave like a bacterium. Pasteur coined the term “virus,” after the Latin word for “poison,” to describe such agents. In 1898 Dutch engineer and bacteriologist Martinus Willem Beijerinck (1851–1931) confirmed Iwanowski's results and isolated the tobacco mosaic virus.

Cell Theory and Cellular Pathology

Cells are the microscopic living units of biological tissue. Because their outer membranes give them each a clearly demarcated shape, English scientist Robert Hooke (1635–1703) coined the term “cell” in *Micrographia* (1665) to describe them. For the next 173 years scientists studied cells meticulously and made accurate observations of their structure but formulated no plausible account of their origin, growth, or purpose. Highlights of this era include German biologist Karl Ernst von Baer (1792–1876) discovering the ovum in 1827 and Scottish botanist Robert Brown (1773–1858) naming the nucleus in 1833.

Working together, German botanist Matthias Schleiden (1804–1881) and German physiologist Theodor Schwann (1810–1882) founded modern cell theory in 1838, when they proposed that cells are simultaneously both distinct living entities and the components of all larger living things. Schleiden and Schwann built their theory on the observations of Hooke, Dutch microscopist Anton van Leeuwenhoek (1632–1723), Brown, and German naturalist Lorenz Oken (1779–1851). Although revolutionary, their work was full of mistakes. Schleiden thought that the cell wall was rigid and solid rather than a permeable membrane and that the nucleus was attached to it. The major flaw in their system was that they continued the old belief that cells arose by spontaneous generation from nonliving matter.

With microscopes steadily improving, knowledge of cell structure increased rapidly throughout the nineteenth century. In 1837 German anatomist Friedrich Gustav Jakob Henle (1809–1885) described the epithelium of various tissues, that is, the cell structure of their mucous membranes. He also pioneered classifying tissues according to their cell structure. Yet scientists in the early nineteenth century made little headway toward understanding cell chemistry or physiology.

Czech anatomist and physiologist Jan Evangelista Purkinje (1787–1869), the first to use the microtome, an instrument used to cut biological specimens into very thin segments for microscopic examination, discovered the ganglionic cells in the cerebellum that are named for him and coined the term “protoplasm.” German

Rudolf Virchow was a nineteenth-century German pathologist, regarded today as the founder of cellular pathology. (Library of Congress)

➤ “ALL CELLS COME FROM CELLS”

Virchow’s famous dictum “All cells come from cells” derives from Remak’s rejection of the belief that cells could freely arise from either tissue or environment. The concept is known as either Virchow’s law or the Remak-Virchow law. The Latin phrase itself, “*Omnis cellula est cellula*,” was coined in 1825 by French chemist François Vincent Raspail (1794–1878). Virchow developed his cell theory as a professor of pathological anatomy at Würzburg from 1849 to 1856 and was chiefly influenced by Scottish anatomist John Goodsir (1814–1867), to whom Virchow dedicated his 1858 magnum opus. Virchow, rather than Remak, gets most of the credit for the insight because he analyzed and synthesized previous theories into a coherent whole.

—Eric v.d. Luft

botanist Hugo von Mohl (1805–1872) continued Purkinje’s research on protoplasm. Oken’s student, Swiss botanist Karl Wilhelm von Naegeli (1817–1891), studied its chemistry. German zoologist Maximilian Schultze (1825–1874) demonstrated in 1861 that protoplasm in any kind of cell is essentially the same. In 1867 German biochemist Moritz Traube (1826–1894) published on osmosis and cell membrane permeability.

Cell division as the means of cell reproduction was discovered gradually by many scientists working independently of one another. Mohl described cell division in 1851. Polish physiologist Robert Remak (1815–1865) made several important discoveries, mostly concerning embryonic and nervous system cells. In 1852 he published his theory that cell division causes tissue

growth. German physician Walther Flemming (1843–1905), who coined the terms “chromatin” and “mitosis,” was among the first to use dyes to study cell structures. He wrote a classic account of cell division in 1879, as did German botanist Eduard Adolf Strasburger (1844–1912) in 1880. Swiss zoologist Albert von Kölliker (1817–1905) was the first to apply cell theory to embryology. He showed that spermatozoa are cells and later postulated the cell nucleus as the locus of heredity.

Cellular pathology is the study that correlates diseases with changes in cells. German physician Rudolf Virchow (1821–1902), the greatest pathologist since Giovanni Battista Morgagni (1682–1771), founded this study in 1858 by publishing *Die Cellularpathologie in ihrer Begründung auf physiologische und pathologische Gewebelehre* (*Cellular Pathology Based on Physiological and*

Pathological Histology), one of the most influential books in the history of medicine. Virchow defined health and disease respectively as the normal and abnormal states of cells.

ERA 8 Crisis and Achievement, 1900–1945

The period between 1900 and 1945 was a half century of remarkable achievement, with widespread advances in science, technology, and medicine as well as general economic growth and expansion, but it was also a half century of crisis characterized by total war, genocide, global economic depression, and the oppression of millions by totalitarian regimes and colonial exploitation. The twentieth century opened with a period of western European dominance as well as one of scientific breakthroughs and new social and intellectual possibilities. Europeans entered World War I with a sense of exhilaration, but a very different mood emerged afterward. The brutality of mechanized warfare shocked the intellectual elite, inspiring unsettling trends in art and an intense interest in the “new science” of psychology, especially psychoanalysis. The new physics introduced by Albert Einstein, Max Planck, Werner Heisenberg, and others made the world feel somewhat less solid, while advances in nuclear technology, particularly in weaponry, made it more tense. The disaster of World War I and the economic changes brought about by financial systems of growing complexity added to the sense that the world was entering into a new age. The implied philosophy of modernism, with its uneasy relationship with the technological age, accompanied accelerating industrialization, consumerism, and popular culture. Advertising reinforced the sense of dynamic change with its message that old values (such as thrift and self-denial) should be left behind in favor of the quenching of desires.

Western European Hegemony

During this period, Europe rose to its zenith of power in global affairs. Europe was in political and economic control of 85 percent of the earth's surface by 1914 via colonization and the development of transnational commercial networks. However, by 1945 this European hegemony was in tatters, reeling from the aftermath of two world wars, a global economic depression, political and social revolutions, and the diffusion of new ideological movements. To a lesser extent, the United States and Japan also entered the fore as global powers in the late nineteenth century. However, it was Britain, France, and Germany that held imperial dominance over much of the world through the establishment of vast overseas empires, effectively establishing a European-centered world system.

The other two major eastern European Great Powers, Russia and Austria-Hungary, also held on to the vestiges of power in spite of their long-term decline. Tsarist Russia maintained a contiguous land empire that straddled most of Inner Eurasia and vast portions of eastern Europe

and the Far East. Habsburg Austria-Hungary was reluctant to relinquish its hegemony in central Europe and the Balkans but had to contend with the rise of Slavic nationalism that sparked World War I. Other European powers, such as Italy, Belgium, the Netherlands, and Spain, also held lands abroad, if only to maintain the trappings of imperial prestige despite their relative decline in relation to the ascendancy of the Great Powers.

In 1900 much of East Asia, Africa, the Middle East, and Latin America were under either direct or indirect forms of European dominance. Forced treaties, extraterritoriality, and gunboat diplomacy ensured that the Ottoman empire and China were vulnerable to European economic dominance. Indirect economic control of the Latin American republics made countries such as Mexico, Argentina, and Brazil dependent on decisions made in the financial centers of Europe. Direct political control, through either proxy states or colonial governments directly accountable to European authorities, characterized European hegemony in much of Southeast Asia, Oceania, and sub-Saharan Africa. The most notable example, the British Raj in India, ruled over millions of Indians with a British bureaucracy in the tens of thousands, with levels of autonomy that ensured that the system worked with the compliance of local authorities. European institutions and culture influenced much of the world in terms of fostering technological development, consumer cultures, and other facets that characterized European civilization, albeit at varying levels throughout many of the world's regions. Exceptions, such as Thailand, Japan, and Turkey, were able to maintain their nominal independence by accommodating themselves to the existing European international system. Regardless, the exploitation of labor and the expropriation of raw materials were central elements of European dominance, something not lost on European educated elites of these colonial domains who were to figure in anticolonial struggles, such as Mahatma Gandhi, Franz Fanon, and Ho Chi Minh.

Despite rapid technological, scientific, and philosophical innovations in much of the Atlantic world, the convulsions of this period ushered in a new era no longer primarily shaped by European developments and expansion.

However, by 1945 European hegemony had been depleted with its vast colonial edifice gradually crumbling amid the stirrings of revolution, nationalism, and warfare. Two world wars, a global economic depression, and the onset of ideological movements such as nationalism, fascism, socialism, and communism that encouraged belligerence as well as anticolonial movements all eroded the global dominance of the European Great

Powers. World War I was effectively a European civil war fought on a global scale, including in colonial holdings and with colonial troops in Europe. In World War II, the Japanese drive for supremacy in Asia and the Pacific, when added to the imperialist designs of Nazi Germany and fascist Italy, was an additional source of destruction and widespread human misery. Despite rapid technological, scientific, and philosophical innovations in much of the Atlantic world, the convulsions of this period ushered in a new era no longer primarily shaped by Eu-

ropean developments and expansion. By the end of World War II, the United States and the Soviet Union emerged as the major world powers. With the collapse of European colonialism, new powers such as China, India, and Brazil also began moving into international prominence. Western European dominance over world affairs ended, although the region would again become a major economic force in the 1960s and beyond.

Ideology

The history of this period can also be understood by examining the ideological forces that influenced world events, specifically the many varieties of nationalism; the faith in technology and modernization; the contrasting political ideologies of liberalism, fascism, and communism; and the many varieties of the philosophy of modernism.

Nationalism, which had been born as Europeans forged new political relationships, now shaped European conceptualizations of the relationship between the nation and the state, focusing attention on the bonds between a people and its governing apparatus. In European nationalism, this bond was largely defined via the terms of shared culture, race, and institutions. Such notions—with their abilities to unite and to isolate—also spread over Europe’s vast empires abroad. While other factors, such as economic competition, colonial disputes, and arms races, fueled the European drive into World War I, nationalism played a significant role in uniting populations in support of conflicts that resulted in the loss of tens of millions of lives. Nationalism, both as a contributing cause and a direct result, played a part in the Russian Revolution, the German Revolution, and the collapse of the last bastions of the Old Regime in eastern Europe and southwest Asia. National identities, supporting a concept of a collective identity, sometimes supported and sometimes came into conflict with Lockean liberalism and its focus on the rights of the individual.

During this period, the economic and social philosophy of liberalism, which had accompanied the rise of free trade and capitalism as well as the free exchange of ideas in scientific communities, came under fire. Liberalism also underpinned notions of representative government and the worth of the individual in such polities. The Bolshevik Revolution and its idealistic underpinnings, inherent critique of social inequities (i.e., class conflict), and positive initial presentation by elites in other countries made communism a viable alternative to economic liberalism and even more attractive during the Great Depression of the 1930s, when capitalism appeared to some as a god that had failed.

In addition to communism, during the interwar period fascism also emerged as a major ideological force contesting liberalism and the failings of laissez-faire capitalism when not harnessed specifically to a state apparatus. As with communism, fascism became attractive during the economic disaster of the 1930s. States such as Britain and the United States avoided political revolution, while these emerging ideologies transformed countries such as Germany, Russia, and Italy. National Socialism

(Nazism) in Germany, fascism in Italy, and Marxism-Leninism in Russia (the Soviet Union after 1922) became models for much of the rest of the world to follow, with many backers and true believers. Imbued with ardent nationalistic fervor, fascists and Nazis advocated a strong state, militarization, and a vast regimentation of the national population. Similarly, communists sought to bring an end to the capitalist domination over Europe and to create a dictatorship of the proletariat, while the Comintern promoted communist movements abroad.

Nationalism fueled anticolonial struggles across the globe. The Chinese Republic of 1911 replaced the Qing dynasty, but no faction was able to establish clear leadership or deal effectively with regional power centers or the Japanese. The Chinese Communist Party, eventually led by Mao Zedong, also emerged as a major contender for power in China. Similarly, the Mexican Revolution of 1910 eroded the authoritarian regime of Porfirio Diaz but in subsequent decades lost its momentum as it succumbed to one-party rule. Indian nationalism in British-ruled South Asia was driven by British reluctance to allow for greater self-rule or outright independence. During the interwar period, much of the colonized world was imbued with a greater sense of national identity as European- and American-educated elites returned with the ideological lessons learned in universities and political parties. World War I and the Great Depression further stirred anticolonial sentiment. Nazi Germany, fascist Italy, imperial Japan, and the Soviet Union sought allies by promising economic, diplomatic, and military assistance to counter European domination in the colonized world.

Bolstered by breakthroughs in science and technology, modernization also became one of the new faiths of this period. Modernization encompassed a general ideology of progress based on the introduction of new technologies as well as medical and scientific advancements, all of which, when spread, could improve quality of life and transform a region and its peoples. Modernization included the introduction of new forms of production (industrialization and its infrastructure of railroads, roads, improved port facilities, communication networks, and educational institutions), new products and forms of entertainment, and new weapons systems. Initially associated with the ideologies of liberalism and imperialism, modernization was also embraced by fascists and communists, all of whom promised the benefits of modernization without any of the social malaise they associated with decadent liberalism.

In the colonized and developing worlds, modernization was part of imperialism in both its direct or indirect forms. Nevertheless, most nationalists, from the Americas to eastern Asia, viewed modernization as a necessary means toward economic independence from Europe and thus co-opted it as part of their drive toward national independence and autonomy. In this context, the project of modernization developed into different trajectories in various world regions related to ideological or national liberation movements. The Soviet model of modernization and its cheery representations by true believers, when contrasted with the collapsing economical structures of Europe and the United States (which despite the New Deal was struggling well into the beginning of World War II), proved to be an attractive model to follow for much of the world

struggling with a global economic crisis. Depictions of the massive industrialization that followed Stalin's Five-Year Plans, designed to accelerate national development under socialism, suggested the new possibilities of modernization in countries freed from European colonialism and financial domination. However, domestic developments in the Soviet Union (including the Russian Civil War, forced collectivization, the Great Terror, and mass starvation in Ukraine, among other major catastrophes) were far grimmer than the illusion of a socialist paradise promoted by socialists and communists abroad.

Rapid modernization from 1900 to 1945 reshaped society and culture. Revolutionary innovations such as the discovery of the X-ray (1895), electrification via alternating current, the development of the assembly line and mass production, and the development of the automobile, the airplane, the telephone, and the radio as well as scientific breakthroughs such as Albert Einstein's theory of relativity, Edwin Hubble's discovery that the universe was expanding, and the early rumblings of quantum physics bedazzled the public, intellectuals and laypeople alike. The philosophy or aesthetic movement of "modernism" that coalesced in this period in the arts, thought, and literature had several major trajectories. One trajectory, aligned with liberalism and clearly expressed in architecture, embraced the new possibilities and methods of construction of the machine age and encouraged a rationalization in building design and in urban and industrial planning. Another trajectory, primarily aesthetic—and therapeutic, as seen in the Dada and later Surrealist movements in art and literature—expressed a revulsion against World War I and its killing fields and a rejection of the machine and industrial automation as dehumanizing. Instead, the proponents of Dadaism and Surrealism embraced notions of the subconscious, the irrational, and spontaneity. Modernism was also reinforced by the development of mass culture. Mass advertising encouraged a free-floating desire and the rejection of traditional restraint on behavior. A new taste for thrills and pleasure accompanied the Jazz Age and its new entertainment forms, such as automobile racing and joy rides, the exhibitions of aerial daredevils in airplanes, and roller-coaster rides at amusement parks. This embrace of the machine not for its rationality but for its thrill factor and its new possibilities for individual identity also figured in an important variant of modernism. This modernism rejected the liberal project, including the sanctity of the individual. The modernist vision was expressed early in the Futurist movement, with its proponents, particularly Filippo T. Marinetti, expressing a taste for fascism and a future in which humans and machines could blissfully fuse. This rejection of liberal individualism had another important adherent in the later thought of psychologist B. F. Skinner, who posited that the ideal society must be engineered to lessen conflict. Other authors, however, expressed their apprehensions regarding the emergent

Depictions of the massive industrialization that followed Stalin's Five-Year Plans, designed to accelerate national development under socialism, suggested the new possibilities of modernization in countries freed from European colonialism and financial domination.

new world. Such fears are reflected in the works of authors such as George Orwell, Franz Kafka, and Aldous Huxley, who presented grim pictures of future dystopias in which political ideologies and modernization would completely shape humanity's destiny, with little to no regard for human life or liberty.

The following discussion looks at how the changes of the period from 1900 to 1945 unfolded in key world regions and, in particular, at the interplay between political change and ideological forces. An emphasis on military affairs is unavoidable given the eruption of two world wars in this period.

Sub-Saharan Africa

From 1900 to 1945 the vast portion of sub-Saharan Africa was under the direct rule of Britain, France, Italy, and Germany (until 1918 when Germany's colonies were seized). Following the European Scramble for Africa in the late nineteenth century, sub-Saharan Africa effectively became a chessboard for European diplomacy, with Germany seeking to gain territories at the expense of Britain and France. However, it was France with its immense French West Africa and French Equatorial Africa domains and Britain with its vast north-south expanse from Egypt to South Africa that characterized much of sub-Saharan Africa during this period. Africa was a critical element of Europe's global empires in terms of its vast natural resources and its large labor pool. The Boer War (1899–1902) was effectively a British attempt to ensure its hegemony in its dominions in South Africa (Union of South Africa after 1910) after skirmishes over the diamond trade and inland trade routes. This conflict illustrates the importance of Africa to European markets and Europe's strategic objectives in this period. Allowing this region to become autonomous would have created the potentiality of it falling into German influence, something the British could not allow, as this was a valuable strategic chokepoint on the sea-lanes to British India.

The campaigns in Africa during World War I were very different from those in Europe. While great armies vied in Europe, in Africa most engagements were more limited, fought by companies rather than divisions. Artillery was not as important in African fighting. Within Africa, most of the troops, especially those used by Germany, were native Africans. Overall, more than one million African soldiers participated in military campaigns. With the end of the war European colonial authorities returned, in fact increasing their domains by taking over German lost territories under the League of Nation's convention of mandate rule. The most profound and long-lasting impact on Africans may have been the realization that they could fight Europeans as equals, if given adequate arms, and thereby destroy the carefully cultivated mythology of European invincibility.

The global economic depression of the interwar period had a much more limited impact on the economies of this region insofar as European economic dependence was manifest. Many Africans found themselves at the whim of the European economic world system, with their lifeways

and livelihood dependent on events occurring in Europe. Italian attempts to conquer Ethiopia were ultimately successful (though short-lived) due to Italian technological advantage, but stubborn Ethiopian resistance, despite its technological and military disadvantage, characterized this conflict. In World War II, Africa was important not only because it was a source of materials and manpower but also because of its strategic locations, such as the Suez Canal. Most of the actual fighting in this war took place in the French colonies of North Africa. Mussolini's troops invaded Egypt from Libya, but the Axis forces were finally defeated in Africa in May 1943. There were no theaters of operations in South Africa during this time.

By 1945, assertive emergent nationalist leaders were aware of the weakened and economically devastated European powers. Regardless, decolonization would not begin in full force until the decades following the end of the war. However, British and French colonial structures were already on the decline, with many European-educated Africans demanding greater autonomy in recognition of their efforts in assisting in the war effort. Nationalist movements, often with ideological support from the Soviet Comintern, sought and worked toward the dismemberment of European imperialism and eventual national independence.

Italian attempts to conquer Ethiopia were ultimately successful (though short-lived) due to Italian technological advantage, but stubborn Ethiopian resistance, despite its technological and military disadvantage, characterized this conflict.

The Mediterranean Basin

From 1900 to 1918, the Ottoman empire faced a long-term decline and was the object of European colonial ventures directed at its extensive domains along much of the eastern and southern Mediterranean littoral. The Balkan states of Greece, Serbia, and Bulgaria sought to gain the Ottoman empire's remaining European territories, which were effectively seized in two Balkan wars. Britain, France, and Italy had already acquired many of the Ottoman empire's former North African provinces, allowing it only nominal authority in these regions. Increasing German influence, due in part to the planned construction of the Berlin-to-Baghdad railway to ensure German access to Middle Eastern oil, led to the Ottoman empire joining with the German-led Central Powers in World War I.

The Turkish state—installed by the Young Turks to replace the collapsing Ottoman empire—lost the war but outlasted the Ottoman regime. While Turkish troops fought bravely against better-equipped British, British commonwealth, and British Indian troops, a surprising Turkish victory at Gallipoli was instrumental in launching the career of Mustafa Kemal (1881–1938). During this time, the Young Turks orchestrated the Armenian genocide to create a more ethnically homogenous Anatolia in the midst of war. After the fighting concluded, arrangements concerning the Ottoman Turkish homeland were complex. The treaty called not only for the loss of Balkan and Arab lands but also for the surrender of much

of the Anatolian homeland. Kemal, the Turkish hero of Gallipoli, organized an army that drove British, French, Greek, and Italian forces out in 1920 and established the Republic of Turkey. In 1935 the National Assembly gave him the honorific “Ataturk,” which means “Father of the Turks.” As for the other Ottoman lands, at the end of World War II the question was referred to the newly created League of Nations. Great Britain and France were assigned the Ottoman Arab territories through mandates, under the terms of which they would control these former Ottoman territories until their populations were ready for self-rule.

Disregarding promises of independence to Arab nationalists in exchange for assistance against the Ottoman military, British and French authorities sought to divide the former Ottoman Middle East between themselves, having already established oil companies to exploit much of the region’s wealth. Furthermore, the establishment of a Jewish homeland under British auspices in Palestine stirred tensions in the region. Palestinian Arabs viewed this as a form of colonialism, as large numbers of Zionists settled in the interwar period. Turkish Anatolia and Thrace, however, were able to maintain sovereignty despite European ambitions to carve up remaining Turkish territories. However, the interwar Middle East was now part of the European world system, shaped mostly by the British-French rivalry in the region as well as Zionism.

With the onset of World War II, North Africa and the Middle East became pivotal battlefields for the major belligerents, with National Socialist Germany and fascist Italy seeking support among nationalist leaders who wished to resist British and French colonial rule. Notwithstanding their independence in 1932, Iraq and Iran were put under indirect British and Russian control, respectively, to prevent them from coming under German influence. The Middle East remained solidly under Allied control throughout the war despite diplomatic flirtations between Arab and fascist leaders, most notably the mufti of Jerusalem’s infamous meeting with Adolf Hitler in 1941. Various battles were fought in North Africa between Allied forces seeking to break German general Erwin Rommel’s tank forces. Large numbers of Arab and Maghreb colonial troops fought with British, American, and Free French forces in North Africa and Europe, seeking greater autonomy after the war. Arab nationalists were encouraged at their prospects after observing their European colonial overlords as vulnerable both at home and abroad. By 1945 much of the region remained under European dominance, although weakened and facing increasing demands on the home front. As a result the ebbing of European hegemony was already evident, and decolonization was soon to follow, albeit creating further instability in the region when the British vacated Palestine in 1948, leaving the Arab-Israeli issue unsettled.

South Asia

From 1900 to 1945, most of South Asia was under British domination through both indirect and direct colonial control. British India (which constitutes modern India, Bangladesh, and Pakistan), Ceylon (modern Sri Lanka), and the Maldives were integral elements of the British empire. The British Raj was considered the “jewel” of the British empire,

as it ensured control of a large market for British manufactured goods as well as a viable pool of labor for the British economy. Through varying degrees of political and economic control, British colonial authorities were able to maintain power over a vast region, utilizing regional resources such as Indian troops while maintaining a minimal bureaucracy. However, British authorities confronted an increasingly resentful Hindu, Sikh, and Muslim population. Despite efforts by the British to weaken the anticolonial movement in India by supporting the Muslim League against the Hindu-majority Indian Congress, Indian nationalists, such as Mahatma Gandhi, pressed British authorities for outright independence.

During World War I, British Indians fought for the British empire, mostly in the Middle Eastern theater of operations and to a limited extent on the western front. In spite of their efforts, however, British Indians were still considered mere adjuncts of the British empire and not in any way ready for independence. As a result, interwar

British India was plagued with discord and frustration, as both Hindus and Muslims became active in seeking greater autonomy from Britain. With the world thrown into economic instability during the Great Depression, some Indian nationalists found the ideologies emerging from Europe, such as fascism and communism, attractive alternatives to British colonialism. Moreover, Japanese overtures and descriptions of a Japan-dominated “Asia for the Asians” made South Asians realize that collusion with Japan’s Greater East Asia Co-Prosperity Sphere was a viable course of action. Despite British efforts to counter such external attempts to encourage Indian nationalist ambitions, resentment of the British fostered a significant number of political movements aimed at independence. With the widespread repression of nationalist leaders in British India in the interwar period, most notably Gandhi and other Quit India movement leaders, most Indians came to view British colonialism with increasing resentment, and resistance increased.

During World War II, as with World War I, most Indians aligned themselves on the side of Britain, this time against Germany and Japan, hoping that such allegiance would gain India independence from Britain at the war’s end. With the severe weakening of Britain as a result of the war, Indian and Ceylonese nationalists worked toward their independence ever more fervently. However, the rivalries between Hindus and Muslims in India created a new set of issues that would affect how eventual independence would play out in the period immediately following the end of the war in 1945.

Despite efforts by the British to weaken the anticolonial movement in India by supporting the Muslim League against the Hindu-majority Indian Congress, Indian nationalists, such as Mahatma Gandhi, pressed British authorities for outright independence.

East Asia

At the dawn of the twentieth century, Qing China remained nominally independent. The growth of European spheres of influence, extraterritoriality, and unequal treaties—which had resulted from the Opium

Wars in which China fought unsuccessfully against Britain—hampered this independence. British, French, German, Russian, and Japanese extractions of territory and economic concessions from China led to increasing resentment among the rank and file of the Chinese population toward the Europeans and the Manchu Qing dynasty in power. Rising nationalism was evident in new social movements aimed at both overthrowing the Qing and driving out the Europeans. Most notably, this was evident in the Boxer Rebellion, an effort to confront European colonialism, that ended in 1902 when European, Japanese, and U.S. troops quashed Chinese nationalist efforts in Beijing.

In contrast to China, Meiji Japan managed to escape European colonial domination and to create its own empire in East Asia at the expense of China, Korea, and Formosa (present-day Taiwan). Japan's standing increased after its military victory over a European Great Power, Russia, in 1905. Following the Meiji Restoration of the late nineteenth century, Japanese authorities had found it expedient to modernize, industrialize, centralize power, and foster a heightened sense of national identity in order to counter European encroachments on Japanese sovereignty, especially in light of developments in China.

In 1911 Chinese nationalists under the leadership of Sun Yatsen were successful in overthrowing the Qing dynasty and established a nominally republican government under the leadership of Yuan Shikai. Yuan declared himself emperor in 1915, but the new government fell apart at this death in 1916. Despite Sun Yatsen's efforts at national unification and modernization, China's provinces remained outside of the political center of Beijing and managed to maintain varying levels of power under various warlords, creating instability across much of the country and leaving it at the whims of European colonialism. However, the outbreak of World War I, for which China provided laborers to as-

sist the Allied effort, led to Germany's loss of former domains in China. The Chinese had expected those lands to be reincorporated into China proper, but they were awarded to Japan. The student protests over that, known as the May Fourth Movement, was the first dynamic expression of Chinese nationalism. Nevertheless, after the war Japan became more aggressive in its foreign policy vis-à-vis China, seeking to gain control of Manchuria. Humiliated

The Chinese had expected those lands to be reincorporated into China proper, but they were awarded to Japan. The student protests over that, known as the May Fourth Movement, was the first dynamic expression of Chinese nationalism.

by European and American attempts to control Japanese naval expansion, Japanese military authorities sought to expand in the politically unstable China.

Intra-Chinese fighting between the Nationalists (Guomindang, or GMD), under the leadership of Jiang Jieshi (Chiang Kai-shek), and the Communists, under various leaders until Mao Zedong emerged as a clear leader in 1935, added a further layer of complexity to the instability of China. The Great Depression created an economic justification for expansion that propelled Japanese militarists to plot against China by staging a series of incidents designed to provoke war and so seize terri-

tories. Viewing European protectionist measures and closing markets as threatening to the Japanese economy, Japanese militarists deemed territorial expansion necessary. The establishment of the state of Manchukuo (1931) in Manchuria and Inner Mongolia and alliances with Chinese warlords against the central authority of Jiang Jieshi allowed Japan to trigger the Pacific War (1937–1945), which would become one of the two main theaters of World War II.

During World War II, in tandem with its war against China, Japan expanded at the expense of French, Dutch, and U.S. colonies in Southeast Asia and created the Greater East Asian Co-Prosperity Sphere under Japanese hegemony. The vastness of Chinese geography prohibited the conquest of the entire country and offered a refuge from which resisting Chinese troops could continue the struggle. In addition, tenuous cooperation between Nationalists and Communists during the war helped them maintain a level of national cohesion to resist Japan. After the entry of the United States into the war following the Japanese attack on Pearl Harbor in 1941, Allied assistance also helped prevent Japanese advances into mainland China.

With the Japanese surrender of 1945, the Pacific War was effectively over, but the Chinese Civil War effectively resumed as the Nationalists and the Communists vied for control of the country (given that initial hostilities had begun in 1927 and were merely placed on hiatus as a result of Japanese aggression). Japan, following surrender, lay in utter ruin and was occupied by Allied forces. With the end of World War II, most of East Asia was characterized by physical ruin and political instability brought on by decades of warfare. Moreover, the region faced yet another war, in Korea (from 1950 to 1953), until a United Nations agreement established an artificial demarcation at the 38th Parallel, effectively creating two Korean states.

Southeast Asia

The vast expanse of Southeast Asia was mainly under European and U.S. colonial domination during this period. French Indochina (Vietnam, Laos, and Cambodia), British Malaya (Malaysia), Burma (Myanmar), Singapore, the Dutch East Indies (Indonesia), and the American-ruled Philippines were all under direct domination of Western colonial authority. At the beginning of the century, the United States had fought a war of attrition (1898–1902) against Filipino nationalists after having ousted the Spanish from the Philippines in the Spanish-American War (1898). Thailand was a clear exception, given its geographical location as a buffer between British and French territories. World War I played a minimal role in events in Southeast Asia, as these countries were far from the battlefronts. However, the Great Depression and interwar ideological influences, primarily from Japan, had a significant impact in Southeast Asia. Despite frustrated efforts at greater autonomy after the Wilsonian promise of national self-determination was not extended to the nonwhite nations of the world, nationalist leaders such as Vietnam's Ho Chi Minh maintained relationships with the Soviet Comintern

revolutionary movement abroad to ensure funding and clandestine activity against the European colonial authorities.

World War II drastically altered the colonial structures of Southeast Asia as the Japanese ousted French, British, Dutch, and American forces from the region. Notably, the Vichy French, as a satellite of Nazi Germany, handed over control of Indochina to Japan. While Japan attempted to allay the fears of these countries by promising them a place in its Great East Asian Co-Prosperity Sphere, exploitation and military excesses illustrated Japanese racist preconceptions regarding fellow Asians. However, some nationalists, such as Indonesia's Sukarno, were able to use the Japanese occupation as a means to maintain greater autonomy than that known under European control. While many Southeast Asians fought with the Allies against the Japanese, after having seen their former European colonial masters ousted and having seen a fellow Asian power rise to prominence in the region they were reluctant to allow the postwar return of European colonial rule. As a result, with the widespread development of nationalism in the region and with varying levels of Soviet influence and aid, Southeast Asia became a hotbed of rebellion and revolution in the next several decades.

Inner Eurasia

In 1900 much of Inner Eurasia was under the direct political domination of tsarist Russia. From the Russian Far East through the steppes of Central Asia and Siberia to the Caucasus and the Baltic littoral, Russian authorities ruled a vast state of myriad ethnicities and religions. However, the political fragmentation, exacerbated by the Russo-Japanese

The Russian Revolution of 1905, while quelled with fierce repression and false promises of greater liberalism, did not upset the Russian autocracy but did inflame social and political movements toward the removal of the existing regime.

War of 1905, led to ever more resistance against the tsar. The Russian Revolution of 1905, while quelled with fierce repression and false promises of greater liberalism, did not upset the Russian autocracy but did inflame social and political movements toward the removal of the existing regime. Russian ambitions in Europe and its growing involvement in Balkan affairs led to its involvement in World War I. However, the lack of viable stores of

weapons, depleting morale, and growing tensions in the countryside and the cities led to ever-growing resentment against the autocracy.

Despite a series of victories against the Germans and the Habsburgs late in 1916, the Russian empire fell apart in February (March in the Gregorian calendar) 1917. The February Revolution created the Provisional Government in lieu of the abdicated tsar, with the prospect of continuing Russia's participation in World War I and maintaining stability amid deteriorating conditions. In the interim the Bolsheviks plotted its overthrow, which they successfully executed in October 1917, thus completing the Russian Revolution that replaced an autocratic regime with a "dictatorship of the people" that aimed at rebuilding society along com-

munist lines. The promises of peace and bread were subsequently maintained under the leadership of Vladimir Lenin, as Russia made terms for ending the conflict with Germany. The Treaty of Brest-Litovsk of 1917, which ceded vast portions of the former Russian empire to Germany, was seen as a necessary first step to ensure peace for socialist Russia.

However, the forces of reaction would not go quietly, and the Russian Civil War (1917–1923), which pitted the reactionary Whites against the revolutionary Reds, affected most of Russia's Inner Eurasian dominions. Regions in Central Asia and Ukraine that had attempted to create sovereign states amid the civil war were forcibly conquered by the Russian Red Army and were coerced to comply with economic and ideological institutions. While foreign assistance by the Allies to the Whites proved of no consequence, the communist Reds correctly viewed this as an attempt by global capitalism to reverse their gains. With the end of the Russian Civil War, the Red Army was able to regain all the former territories of the Russian empire with the exception of Poland and the Baltic countries. With the establishment of the Union of Soviet Socialist Republics (USSR) in 1922, all these regions came under the political, economic, and ideological control of the Communist Party of the Soviet Union (CPSU). While the USSR economic model sufficed to ensure the provisioning of the Red Army and the day-to-day functioning of the nascent socialist state during the war, Lenin established the New Economic Policy (NEP) in 1921 as a mixed economy of state industries and varying levels of free enterprise in order to rebuild the shattered war-torn Soviet economy.

With Lenin's death in 1924, disagreements over the economic policies of the Soviet Union erupted among the top Bolsheviks. Josef Stalin, the general secretary of the CPSU, was able to oust his opponents and end the NEP in 1928. In its place he enacted vast industrialization state plans and collectivized agriculture. His firm grip over the state police organs and the establishment of a prison system that spanned the Soviet Union allowed Stalin to create an oppressive regime that forcibly coerced citizens to do his bidding. Despite the human cost and the waste created by Stalin's Five-Year Plans and the Great Purges, the Soviet Union was able to industrialize rapidly while destroying the vestiges of the autocracy and eliminating "class enemies." While relationships with western Europe and the United States were contentious amid the suspicions harbored about Soviet machinations through the Comintern and its directives to foreign communist parties, the Soviet Union was able to rejoin the community of nations. The Soviet Union gained admission into the League of Nations in 1933 and also gained a gradual diplomatic recognition by most of the world's nation-states.

Soviet interventions in diplomatic affairs abroad, such as its support of the Spanish Republic during the Spanish Civil War, its invasions of Finland and eastern Poland, and its controversial 1939 Nazi-Soviet Pact with Nazi Germany, raised suspicions of its intentions in global affairs. Following the German invasion in 1941, the Soviet Union entered into a titanic struggle to free its territories from German forces. The eastern front of World War II was characterized by fierce battles between the Soviet Red Army and the German *Wehrmacht* across vast geographic spans and clashes between hundreds of thousands of troops. The Great

Patriotic War, as World War II is referred to in Russia, was the main theater of operations for the Allies as the greatest concentration of Axis forces faced the Red Army from Leningrad to Stalingrad. In coordination with the British and American forces in western Europe, the Red Army was able to close in on Germany through the eastern front, ultimately capturing Berlin in 1945. However, having fought such a bloody conflict at such a high cost, the Soviets were unwilling to give up their gains in eastern Europe.

Moreover, adjacent regions, such as Persia (Iran) and Afghanistan, came under significant Soviet influence during the war. As objects of colonial interest during the preceding period of the Anglo-Russian “Great Game,” during World War II Iran was occupied in the north by the Soviet Union and in the south by Britain to ensure its stability in the face of potential German influence. While these countries were able to maintain their nominal sovereignty, increasing European influence through the interwar period and World War II hindered their foreign relations and domestic affairs to a significant extent. The establishment of British oil concerns in Iran would also foster economic domination based on petroleum profits and the establishment of a pro-British Iranian elite.

Eastern Europe

In the beginning of the twentieth century, the majority of the states of eastern Europe, with the exception of Serbia, Romania, and Bulgaria, were under the control of the Austro-Hungarian empire, the German empire, or the Russian empire. Most of these countries were characterized by rural hinterlands that retained vestiges of feudalism. The major cities were often hotbeds of political revolution and social movements geared at replacing the existing reactionary monarchy and in some instances working for national independence, most notably in the Austrian province of Bosnia-Herzegovina. With the defeat of the Central Powers at the end of World War I, a series of buffer states—Latvia, Estonia, Lithuania, Poland, Hungary, Austria, Czechoslovakia, and Yugoslavia—was established by the Entente Powers to separate western Europe from the Soviet Union. The latter two were artificial constructions composed of myriad ethnic groups that would prove resistant to the development of national identities.

Large numbers of Germans and Jews resided in many of these states, fueling concerns that their otherness was a threat to unified nationalist identities. Nationalist movements, under the influence of fascist Italy and Nazi Germany during the interwar period, fostered anti-Semitic propaganda encouraging countries to remove their Jewish citizens. Moreover, Nazi Germany used German citizens in eastern Europe as an excuse to intervene in the affairs of the region. With the onset of World War II, many of these eastern European states either became German satellites or were forcibly occupied as part of the Third Reich. With the implementation of the Final Solution throughout the Third Reich, the Jews of eastern Europe were removed and initially placed in urban ghettos and

then transported to death camps, where they were shot or gassed en masse or exploited as forced labor for German war production. The large number of eastern European collaborators in the Holocaust during this period is indicative of the prominence of anti-Semitic and anti-Soviet sentiment in the region. With the Soviet conquest of the region during 1945, many of these states came under the ideological control of the Soviet Union via puppet regimes that the Soviet military presence helped establish as “Peoples’ Republics.”

Western Europe

In the beginning of the twentieth century, western Europe, along with its institutions, culture, and ideologies, was the prominent world region in terms of the global economy. Through rapid industrialization, urbanization, and modernization as well as scientific and technological innovations, Britain, France, and Germany were the world’s foremost world powers. While other countries, such as Italy, Spain, the Netherlands, Belgium, and the Scandinavian countries, were second-tier powers, they participated in much of the economic successes of western Europe. While colonial conflict and intra-European rivalries shaped the relationships among Britain, France, and Germany, it was not until the outbreak of World War I that the edifice that had been gradually built over the past century began to fracture.

World War I pitted the economic and demographic resources of the Entente and Central Powers, particularly evident in the western front that straddled the countryside from southern Holland to southern France. Countless artillery barrages ensued, and troops clashed from 1914 to 1918 on an almost daily basis amid squalor and disease. As national economies were directed to the purpose of war, the production of civilian goods was all but halted, leading to shortages of consumer goods and to malnutrition and near starvation on both sides in their respective home fronts. With the end of the war in 1918 and the subsequent vindictiveness enacted through the Treaty of Versailles in 1919, Germany was dismembered, humiliated, and saddled with debt via war reparations demands. Britain and France both struggled to meet their war debts to the United States as well as to pay huge amounts of veteran pensions. At the same time, German economic growth was stagnant, leading to the polarization of politics to the fringe Left and the fringe Right in Germany.

Interwar efforts to buttress the German economy by the United States through the Dawes Plan were undercut by the onset of the Great Depression, which severely gripped western Europe. The postwar popularity of communist, social democratic, and fascist parties was further exacerbated by the severity of the economic collapse. The success of the Russian Revolution inspired many and caused consternation in others. Fascist parties in Italy, Germany, Hungary, and France were able to

With the end of the war in 1918 and the subsequent vindictiveness enacted through the Treaty of Versailles in 1919, Germany was dismembered, humiliated, and saddled with debt via war reparations demands.

make respectable electoral wins in various elections, partly in reaction to fears of Bolshevism. Ultimately, fascist Italy and National Socialist Germany were able to establish revolutionary regimes endorsing egalitarian “classless” dictatorships that embraced nationalism. National Socialism in particular embraced anti-Semitism as a central element of its ideology. Under the leadership of Adolf Hitler, Nazi Germany sought to regain all the losses of World War I for Germany and to wreak havoc on the Jews of Europe. A weakened France and an overstretched Britain were reluctant to engage Germany and thus chose to implement doomed diplomatic policies of appeasement. However, Hitler was intent on war, and World War II began when the pledge to protect Poland on the part of Britain and France was challenged by the German invasion of 1939.

From 1939 to 1943 Germany held the initiative in World War II, making tremendous gains in the first years through the strategy of blitzkrieg (lightning war), which aided in the capture of Poland, France, Belgium, the Netherlands, Greece, and vast portions of the Soviet Union. Britain and the United States, along with the British commonwealth and colonial forces, were able to open major fronts in North Africa and in France, in tandem with strategic aerial bombardment of German targets. Ultimately, in coordinated efforts the Allies were able to defeat the Axis Powers although destroying most of western Europe in the process. Moreover, the former Great European Powers were militarily and economically exhausted, with Germany effectively destroyed and Britain and France unable to maintain their power projection abroad to the same degree as before. As a result, World War II eroded the remnants of European power, making European overseas empires vulnerable to the stirrings of nationalism.

The Americas

Despite their soil being largely untouched by the world wars, the Americas were directly affected by global affairs such as the Great Depression and the relative decline of Europe. The expansion of the United States on the world stage after the Spanish-American War of 1898 was an instance of its growing influence in international affairs. Direct, though delayed, U.S. involvement in World War I was significant in ensuring victory for the Entente Powers. Under the leadership of President Franklin D. Roosevelt, the New Deal was implemented to establish economic growth. Other programs, such as social security, began as a way of alleviating poverty and quelling social unrest. The rapid industrialization and economic mobilization that followed the U.S. entrance into World War II, not to mention the vast workforce reserves in the United States, aided the U.S. recovery from the Great Depression and the country’s engagement on two fronts in World War II. With the end of the war, the United States found that it was a global superpower with a strong economic foundation, a stark contrast with its position at the beginning of the conflagration. Similarly, Canada also emerged from the war as a rising power, having devolved itself from British hegemony

in 1931. As an equal partner in the British commonwealth and no longer a dominion, Canada had benefited from industrial production in the war as well as from its close relationship with the United States in fostering an integral trade relationship.

In contrast, Latin America, while able to benefit from the economic growth fostered by war, found itself under the gradually growing economic domination of the United States as European power waned. In the early twentieth century, Latin American resistance against its neocolonial relationship with Europe and the United States, most notably in the Mexican Revolution, was expressed in myriad ways. However, despite the influence of foreign ideologies, the Latin American republics remained under the grip of their elites, who were bent on repressing foreign ideologies that threatened their wealth and their power. Brazil, Argentina, and Chile established themselves as foremost economic regional powers while maintaining their dependence on foreign markets for their financial stability, relegating them to semiperipheral appendages of the international economy based in the Atlantic world system. Mexico, despite its attempt to break economic domination as facilitated by internal elites by nationalizing its oil industry, nonetheless fell under the domination of a one party-state well until late in the twentieth century. Through much of this period the states of Central America and the Caribbean were vulnerable to U.S. gunboat diplomacy that ensured economic arrangements in line with the interests of U.S. investors. However, with the end of World War II and the establishment of the World Bank and the International Monetary Fund, new economic organs would continue to direct Latin American economic development, fostering a growing dependence on Europe and the United States to a significant extent.

Oceania

Australia and New Zealand experienced vast changes from 1900 to 1945. With their status as commonwealth dominions at the beginning of the century, they both became integral to British military strategy in World War I. The Australian and New Zealand Army Corps (ANZAC) was deployed in the Middle Eastern theater of operations, most notably in the failed operation at Gallipoli. This defeat cemented both Australian and New Zealand national identity. Through the Great Depression, both Australia and New Zealand established welfare states and diversified their economies to meet the demands of the transforming world economy, given their vast natural resources and growing populations. During World War II, despite British disapproval, both Australia and New Zealand worked under nominal U.S. command in the Pacific theater of operations. At war's end, Australia and New Zealand were staunch American allies and were no longer mere pawns in British global interests.

Environment and Population

The period from 1900 to 1945 ushered in massive environmental changes. Population growth, urbanization, mechanized agriculture, and the impact of new technologies such as the automobile, along with the oil and steel industries, revised landscapes. In this period about 600 million acres of rain forest were deforested to make way for farm and grazing land. Water, air, and land pollution became intense throughout industrialized belts, while efforts at abatement were primarily aimed at sewage and drinking water. Elite support for nature encouraged a wilderness preservation movement. The linkage between consumerism, fashion, and species protection became clear in the popular movement to ban the use of feathers from egrets, herons, and other exotic birds in women's hats. The Audubon societies that began with a national chapter in 1886 gained popularity in the outrage over the decimation of bird populations. National forests were set up in the United States, Brazil, Argentina, Chile, Japan, and several European countries. Britain also established preservation societies that oversaw its colonial holdings. The field of ecology was growing in importance, with Germany an important center of ideas. The British Ecological Society was established in 1913, and the Ecological Society of America was established in 1915. By the 1930s the global economic depression, along with the farming disaster of the Dust Bowl in the United States, caused governments to turn toward ecologists as planners. In the United States, for instance, the Soil Erosion Service, established in 1933, in tandem with workers from the Civilian Conservation Corps, attempted massive reengineering of the landscape, ordering land to remain fallow, putting in windbreaks, and instituting other measures to lessen erosion caused by drought, the plowing of marginal (arid) land, and wind.

Issues related to population were of greater interest than issues related to environment. The first half of the twentieth century was the era of statistics and social engineering as far as collecting and analyzing data regarding society and the environment are concerned and also represented attempts to control natural resources and modify human behavior. Governments and corporations started to collect data on practically all human activities, beginning with infant mortality rates and ending with crop yields. Countries, especially the industrialized ones, created bureaus of statistics as government agencies that were given the task of collecting information. For example, Australia created its Bureau of Statistics in 1905, Canada's was created in 1918, and so on. European countries started earlier, while colonies and colonial possessions began later. Population censuses, occasionally taken since the eighteenth century in Britain, now became a regular occurrence every several years. Denmark began to count its own population regularly

beginning in 1901 and every five years thereafter. In Germany the first regular census was held in 1895, while the French statistical office began to study the consumption habits of the population in 1907. Enormous combat efforts during two world wars made it necessary for governments to catalogue their human and natural resources even further in their metropolises and colonies. Elsewhere in Asia and Latin America, developing nation-states also found it expedient to acquire quantitative data for the purposes of economic development and expansion. A new approach to warfare required that military commanders know at any given time what human and material resources they had available. The management of two world wars was social engineering on an unprecedented scale.

The introduction of statistics and the use of applied social sciences as a political tool to solve community problems represented a paradigm shift. Laws of averages and deviations suddenly became paramount in a struggle to define and alleviate social and environmental problems. Critics asserted that by looking at averages and standard deviations, the individual is dismissed. As the amount of information collected increased, computers, invented during the first half of the twentieth century, with their ability to perform millions of numerical operations in a split second changed not only the statistical methods but also the way societies collect and analyze information. Despite the advent of the use of science for what was deemed progress, ideological movements, such as National Socialism and Marxism-Leninism, also applied their own interpretation to support their specific agenda for the purpose of reordering their own societies along ideological lines.

The use of numbers to explain human society could be traced back to the founding of modern applied social science and the desire to understand the changes among the population and in the environment and to manipulate them for humanity's benefit. Sociologist Emile Durkheim achieved fame by using and perfecting the new method of analyzing numbers in order to explain social phenomena. He studied no particular person of flesh and blood but rather an "average man," an idealization among many who suffered from the same social illness. In 1897 he published his study of suicide among a range of social groups. Durkheim, one of the fathers of applied social science, studied the numbers indicating that, on average, suicide occurs more often among widowed or divorced individuals than among married individuals and more often among Protestants than among Catholics. He popularized the modern concept of anomie, a term used to indicate a lack of social integration, and concluded that the less an individual is incorporated into society, the more likely he or she is to commit suicide. Durkheim's kind of study of numbers, which aimed at finding a causal connection to explain the data, became the norm of the newly created applied social sciences, such as criminology.

In the first half of the twentieth century, studies and popular discourse began to focus on the "average man." For example, societies started to measure the "average wealth" of its citizens, expressed as gross domestic product divided by the number of inhabitants living in a state. With the founding of the International Monetary Fund and the

World Bank in 1944, these measurements were finally taken to a global scale in a very systematic fashion. Advocates said that the measurements of population and resources available in nature were used to improve the lot of humankind, increase food production, reduce hunger, and alleviate larger social problems in general. Undoubtedly this was the case. Better measurement and classification of human and natural resources is and was a precondition for their better management. Still, statistics could be very deceiving. On average, two individuals eat meat and potatoes, even if one of them just eats the meat while the other just the potatoes all the time. Despite ideological notions of progress as advocated by ideologues of all stripes, the Great Depression shattered illusions of economic advancement without state tutelage.

Demographic data are the most basic statistical information necessary for any further social and economic analysis. Whereas at the beginning of the twentieth century the population of the world is estimated to have been around 1.7 billion, by 1950 it had reached 2.5 billion. The trend of population growth, though on the rise for centuries, picked up dramatically in the twentieth century. With industrialization, especially the second wave associated with the mass production of consumer goods, the speed of growth increased. In addition to improved incomes and spending powers due to industrialization, declining death rates caused by improvements in sanitation and medical care also contributed to this growth. The pace of growth was awe-inspiring in comparison to preindustrial eras. The earth's population reached its first billion in the 1800s and its second billion in 1930. Even the catastrophic casualties of the two world wars could not reverse the trend. At the end of the twentieth century, there were over six billion people on earth. Population did not grow on all continents at the same pace. In fact, estimates are that the European share of the world population dropped from around 25 percent at the beginning of the twentieth century to approximately 22 percent at midcentury. This drop can be explained primarily by declining birthrates in industrialized areas due to malnutrition and war casualties. All the other continents registered substantial growth during the same period.

No human activity is more closely related to the environment than agriculture. Agricultural activity in the first half of the twentieth century is characterized by a process called intensification, the application of chemical and mechanical aids in order to increase crop yields. For centuries, the population growth of the world was matched by increasing the area of land cultivation. This usually meant clearing up forests. Deforestation in the northern temperate zone (North America and Eurasia) reached its peak by the end of the nineteenth century. Intensification was largely absent because it required modern inventions such as tractors and chemical fertilizers. Predictably, deforestation had its limits and could not be continued indefinitely, especially in very densely populated

Advocates said that the measurements of population and resources available in nature were used to improve the lot of humankind, increase food production, reduce hunger, and alleviate larger social problems in general.

areas of eastern Asia, the Indian subcontinent, and Europe. Therefore, by and large societies managed to meet the demands of a growing world population by using chemical fertilizers, building dams to develop sources for irrigating fields, and using tractors, combines, and other agricultural machines to prepare soil and plant and harvest crops.

Urbanization was the most important social process affecting the lives of millions. The United Nations defined urban areas as settlements with populations larger than 20,000 people. Worldwide, the proportion of urban dwellers grew from 13 percent in 1900 to 29 percent in 1950. People moved to cities because of the economic opportunities they provided, but these obvious advantages were offset by the resulting environmental and social problems found in all large metropolitan areas. The classic German science-fiction film *Metropolis*, directed by Fritz Lang and released in 1927, captured some of the urban anxieties characteristic of the times. The film depicted a lack of communication, inhumane living conditions, alienating technology, a growing gap between rich and poor, and a tendency toward unrest and occasional violence. Even though *Metropolis* was a work of fiction, it reflected the concerns about conditions faced by urban dwellers in the early part of the twentieth century. It is no surprise that Lang was inspired to create his film after he visited Manhattan, one of the most densely populated areas in the world. Moreover, cities in the colonial and developing worlds were also experiencing unprecedented levels of growth as a result of economic investment and the diversification of the global economy in the midst of depression and war.

Governments responded to these increasing social problems in various ways. During World War I, it became obvious that governments would have to effectively mobilize human and natural resources. One way to deal with poverty in particular was to mandate compulsory elementary education. The reasoning was fairly simple. Elementary education was aimed at achieving full or functional literacy, and it would be easier for a literate person to find employment. In many countries this move toward mandatory elementary education happened after World War I, when governments were actively seeking to solve social problems exacerbated by the conflict. As a result, illiteracy rates began to drop gradually all over the world. Left-leaning political and social movements the world over were particularly active in this area, believing that the eradication of illiteracy would lead to better social conditions for the poor. In the Soviet Union of the 1920s, literacy campaigns were turned into veritable crusades, aimed at not only eradicating poverty but also at creating a new “Soviet Man.” Overall, this increased emphasis on mass education had very positive long-term effects on the population. However, this was not the case in many of the regions under European colonial authority, as huge swaths of the population were relegated to performing labor and were deprived of essential education. Despite this, missionary schools and colleges were designed to create a professional class in the colonial movement, with many elites sending their children to the European metropolises for their education.

Local governments were particularly active in solving the health and sanitation problems of modern cities. These local efforts focused on mu-

nicipal water and sewage, which improved and prolonged the lives of many urban dwellers. These advances were, of course, slow in coming. Even today, one-sixth of the world's population lacks access to safe water supplies, and an estimated three million people die each year from waterborne diseases. Industrialized countries, as expected, again led the way. For instance, the city of Tokyo built a municipal water supply in 1889 and a sewage treatment system in 1922. These infrastructural improvements allowed for the reduction of disease and ensured the prevention of epidemics related to pollution.

Two world wars had especially disastrous effects on the population and the environment. Casualty figures were staggering, and they were especially shocking during World War I because it was the first modern war that brought about such a scale of destruction. Chemical warfare was first introduced at Ypres, in northern France, on April 22, 1915. The effects of these weapons were not so significant in terms of casualties, even though those were substantial. The introduction of such weapons indicated a symbolic change for the relatively respectable ethics of war based on honor and chivalry. Again, the new applied social sciences came to play a crucial role. The victory at war depended not on the ideas that the combatants defended or on the dedication and commitment of soldiers to their cause but rather on the cruel laws of statistical averages. Germany did not lose the war on the front as a result of a decisive military victory. Germany actually achieved enormous victories on the eastern front and brought Russia to a complete collapse in tandem with the Russian Revolution. It could be argued that the war was lost for Germany because of unfavorable numbers: its submarines did not manage to sink a sufficient number of Allied supply ships. The blockade of German ports, strictly enforced toward the end of and after the war, brought the defeated Reich completely to its knees, because under those circumstances the state was not able to feed the "average citizen." National war machines fully mobilized their economies and colonies to fight to an unprecedented scale in terms of geographical expanse and available manpower.

While poison gasses were aimed at destroying enemy combatants, other chemicals and methods were used to change and destroy the environment. One of the main casualties of the two world wars was European timber forests. As European forests were being devastated during World War I and World War II, industrial powers began to import timber and other woods from Asia, Africa, and Latin America. Again, everything was in the numbers, and those who could import larger numbers on a consistent basis could better provide for a common soldier and an average citizen. The victory, even though slow in coming, was inevitable. The ability to acquire raw materials and logistically organize such items en masse for the purpose of war was something that would definitively change the level and scope of global economies in the next half century.

Even today, one-sixth of the world's population lacks access to safe water supplies, and an estimated three million people die each year from waterborne diseases.

There were some completely unexpected consequences of the chemicals used for war. The synthetic pesticide DDT (dichlorodiphenyl-trichloroethane), invented in 1887, was used by the armies to clear up and protect front lines located in malaria-infested regions of Africa and Asia even before it began to be used for agricultural production. At the time, it seemed reasonable to overlook the side effects in order to save the lives of millions of soldiers in the tropics. As time went by, it became more obvious that the costs of its usage far outweighed the benefits. DDT was put out of use only after millions of people suffered enormous personal consequences.

Something very cruel and devoid of basic human compassion takes place when wars are fought over numbers, statistics, and export and import quotas and when the casualties and losses on the battlefield are labeled “collateral damage.” Dropping the atomic bombs on the Japanese cities on Hiroshima and Nagasaki in August 1945 clearly illustrates the effect of war on both people and the environment. Hundreds of thousands died, and even more suffered the devastating consequences of exposure to radiation. Agriculture in the affected areas was wiped out for decades. The counterargument was that the dropping of the atomic bombs actually helped to save lives by making the invasion of Japan unnecessary. According to most military estimates at the time, the amphibian invasion of the four Japanese islands would have caused over one million dead and wounded. Still, the moral dilemma at the core of a modern civilization that deals with individuals on the basis of the “average man” cannot be addressed satisfactorily.

and Abraham O. Mendoza*

■ Introduction: Environmental Events

Agriculture is by definition an interaction between humans and nature. Between 28 and 38 percent of the earth’s land surface is used for agricultural production, with roughly one-third of that being used to grow plant food and fiber crops and the remaining two-thirds being used to pasture livestock for fiber, meat, and milk. The activity of agriculture therefore creates the single largest human impact on the natural world.

Through breeding, growing, and harvesting plant and animal crops, humans attempt to mold and alter nature for their own purposes. Because agriculture as an activity combines elements of ecology and society, it affects and is affected by both natural conditions and social factors. Im-

portant political factors shaping agriculture and thereby nature might include, for example, laws regarding the ownership of farmland, acts promoting European settlement in the western United States, or legislation affecting soil erosion and conservation. Economic factors, such as international trade agreements, price supports, and world market prices for agricultural products, produce environmental effects by expanding or contracting the demand for various farm products. Ecological factors, such as climate and soil, also dictate much about farming, but soil quality and climate are also affected by human activities. In short, when thinking about agriculture, it is never possible to separate human factors from natural ones.

One hundred years ago farming was considered an environmentally benign activity that brought people closer to the land. Since that time agriculture has changed, as have attitudes toward farming. Far more often, modern agriculture is seen as ecologically destructive. The entries in this section demonstrate the immense human capacity to alter the natural environment, for better and for worse. Increasing deforestation to create ever more crop and pasture land, reduced species diversity in agricultural areas, soil erosion, and water pollution via runoff pesticides, fertilizers, and animal waste are all examples of negative impacts of modern agriculture. Increasing areas of abandoned or damaged farmland, tremendous levels of water used for irrigation, and decreasing water supplies create increasingly important impacts as well. On the whole, agriculture accounts for 70 percent of contemporary global water use.

Modern agricultural technology is often seen as a major cause of environmental destruction. Historians actively debate the extent to which technology should be seen as an independent cause of change in agricultural history. Some feel that technology is an important factor in and of itself, while others emphasize that technologies are created by people and societies and thus merely reflect the goals and values of their creators. Similarly, climate and geography may be presented as the root causes of the environmental effects of agriculture by some authors, while others see these factors just as possible triggers or contributors to events already set in motion by human politics, economics, and culture. For instance, explanations for an event such as the U.S. Dust Bowl of the 1930s differ in their emphases: Should we consider the root cause to be the human technology of the plow, the climatic event of a drought, the economic pressures of production for a capitalist market, or cultural convictions that rainfall would come if land was turned into farm fields?

How we understand the cause-and-effect relationship between agriculture and environmental change in the past will lead us to different solutions for current problems. Do we prioritize working on new technology, new economic structures and incentives, or new attitudes toward land, farming, and nature?

—*Eva-Maria Swidler*

Agriculture and Environment

Between 1850 and 1945, vast improvements were made to increase crop yield, including more efficient farm machinery, greater application of chemical fertilizers, and usage of genetically modified and engineered seeds, gasoline-powered equipment, and electrification. These factors contributed to the growing impact that agriculture had on the environment during the period 1900 to 1945. Demand for farm produce grew as more of the ever-expanding population lived in urban areas. Some historians have argued that improved efficiency of agriculture promoted rapid population growth, which put pressure on the environment.

Tens of thousands of miles of railroads connected farms, food-processing plants, and busy ports to create a global marketplace for agricultural products. Abundance of crops drove prices down, which in turn increased demand for land. At the same time, as populations grew in Asia, Africa, South America, and Russia, the pressures to open new land for subsistence farming also increased. In the United States, Canada, and western Europe, farms were beginning to shift in ownership from smaller units owned by individuals to large-scale corporation-run enterprises. In the United States, Europe, West Africa, India, Egypt, and parts of Latin America, farms specializing in a single cash crop, such as cotton,

➤ COFFEE AS A CASH CROP

Coffee was one of the major cash crops of the early twentieth century. In Brazil, large swaths of the Amazon River forest were cleared to make land for the growing number of coffee plantations. Like other cash crop systems, Brazilian coffee plantations allowed economic power to become concentrated in the hands of a few wealthy families. The work was performed by poorly compensated laborers. Many were contract farmers who rented land in a manner similar to tenant farming. Others were wage laborers. In either case, they possessed little political power and remained trapped in an intergenerational cycle of poverty.

fruits, vineyards, tea, cocoa, wheat, rubber, coffee, and maize (corn), replaced diversified land usage. As a consequence of these changes, widespread deforestation began to occur in, for example, Southeast Asia with the expansion in acreage of large rubber plantations and in South America with the expansion of the coffee plantations. Such large-scale conversion to cash crops made greater demands for resources, caused more damage to the land, and made pest invasions, such as the boll weevil of the southern United States, more difficult to control.

The ever-growing supply of farm produce often outpaced demand, and peasant and tenant farmers had a difficult time earning adequate incomes and sustaining a living. As the number of farmers increased, wetlands were drained, forests were cut, and grasslands were plowed under to provide more acreage. In doing so, natural climatic regulators were destroyed, and the soil moisture content was dramatically altered. Farming also required significant amounts of irrigation, which washed away valuable topsoil. Forest loss, wind damage, and drought caused further

stress on the soil, and overgrazing by livestock further exacerbated the problems.

Dramatic episodes of soil erosion, called dust bowls, took place in the 1930s. The most dramatic of these occurred on the Great Plains of the United States. The damage was so widespread that it displaced 3.5 million people, who left their land because it could produce no crop. Oftentimes violent dust storms raged for hours, carrying soil as far away as New York City. In the 1930s, similar dust bowl conditions were common in China and in the Sahel region of Africa as the Great Sahara Desert moved southward. At the same time, the loss of watersheds led to flooding when the eroded soil could not absorb above-average rainfall, which in turn accelerated soil exhaustion. As a consequence, farm runoff from soil, fertilizers, and animal waste fouled the nearby waterways.

Governmental policies designed to combat environmental problems caused by agriculture varied in effect. During the New Deal of the 1930s, the U.S. government enacted a series of laws and programs designed to foster soil con-

servation, albeit with moderate success. Not all land-use reforms were as successful. In the Soviet Union, inefficient small-scale farms were forcibly collectivized at the cost of millions of lives due to starvation. European colonial agricultural policy in Africa and Asia was often confused and based more on the needs of the imperial governments than the colonial farmers or the natural environment.

Between 1900 and 1945 global patterns of agriculture had changed. This change was most clearly marked by the rise of single cash crop farming, increased reliance on chemical fertilizers and seeds, centralized government planning, and growing access to a global marketplace.

Forced Collectivization of Agriculture

The implementation of agricultural collectivization in the Soviet Union in 1928, under the regime of Josef Stalin, resulted in the displacement of millions of peasants, the starvation of millions of Soviet citizens, and the destruction of the livelihoods of households that had depended on the land for sustenance. From 1928 to 1933 the Stalinist regime introduced socialism to the Soviet countryside through collectivization under the Five-Year Plan, which sought to increase agricultural production for the purposes of selling produce abroad in order to raise capital to invest in industrialization. Through massive grain confiscations and forced removals of peasants to large state-owned collective farms (*soukhoz'y*), the actual consequences of collectivization were

Soviet poster illustrating the importance of agriculture to the strength of the Soviet state, about 1931. (Library of Congress)

the reduction of total grain output and livestock, thereby resulting in major famines in 1932 and 1933 that decimated the Soviet population.

As Stalin consolidated his power at the top echelons of the Communist Party of the Soviet Union as general secretary in the late 1920s, he sought to move away from the limited private enterprises allowed by his predecessor, Lenin, and encourage the implementation of socialist economic policies known as the New Economic Program (NEP). Stalin advocated a centrally planned economy based on large-scale plans that encompassed the agricultural and industrial sectors, thus allowing for the creation of a fully socialist state. The end of the Russian Civil War in 1923 had resulted in the end of war communism and had allowed for the NEP in order to rebuild the tattered and devastated Soviet economy. By 1928 Stalin viewed the time as ripe to steer the state back into a socialist economic framework.

► DEKULAKIZATION

Dekulakization is known as the Soviet campaign aimed against alleged kulaks, which consisted of widespread arrests, deportations, and executions of millions of suspected peasants and their families from 1929 to 1932. Prosperous peasants, considered class enemies by the state, were labeled as kulaks. Approximately 1.8 million peasants were deported between 1930 and 1931 as alleged kulaks. Soviet officials claimed that it was necessary to destroy the kulaks, as they were counterrevolutionaries and thus a danger to the spread of socialism in the countryside. The destruction of the kulaks was seen as a necessary step for the purposes of state collectivization of agriculture, as they were the ones responsible for widespread hoarding and black marketeering.

On December 27, 1929, Josef Stalin announced a directive calling for the “liquidation of the kulaks as [a] class,” making dekulakization a state-sanctioned policy resolution. The directive called for the execution of certain kulaks responsible for leading resistance efforts against the state, the confiscation of their property and goods, and the forced deportation of millions of other suspected kulaks and their families to forced labor camps in Central Asia and the frozen stretches of Siberia. However, since the label of kulak could extend to anyone possessing any property or showing any resistance to the state, many poor peasants also suffered the trepidations of their respective class enemies.

—Abraham O. Mendoza

In 1928 there was growing demand for grain due to the expansion of Soviet industrial urban centers and the growing needs of the Red Army. However, supplies available to the state were lacking. Stalin alleged that grain supplies were being hoarded by kulaks (wealthy farmers) for speculative purposes. The Soviet authorities immediately authorized a massive requisition of grain from the Russian countryside by police and military authorities. However, grain seizures further discouraged the peasants, leading to reduced grain production during 1928 that, in turn, resulted in further requisitions. By 1929 resistance to the seizures became widespread, with some episodes of violence on the part of authorities in response to massive hoarding and

black markets. The situation became so desperate for the state that anyone caught committing these offenses was subject to the death penalty. Given the situation, the Soviet government under Stalin decided on implementing collectivization in order to break the alleged grip of the kulaks over Soviet agriculture and introduce socialism to the countryside.

In November 1929 the Central Committee decided to implement accelerated collectivization in the form of *kolkhozy* (collective-owned farms) and *sovkhozy* (state-owned farms). This essentially ended the NEP, which had allowed peasants to sell their surpluses on the open market. The state had alleged kulaks transported to collective farms in distant places to work in agricultural labor camps in order to end their alleged influence over poor peasants. However, the criterion for being a kulak was typically anyone hoarding for subsistence or defending their property, which, in fact, meant most peasants. Many peasants, along with their wives and children, perished in transit to or amid the atrocious working conditions within these labor camps. As a result, many peasants began to resist the encroachments of the party and the state police, often by slaughtering their livestock or destroying their crops, thereby resulting in further losses to total agricultural output.

Initially, the collective farms relied on voluntary labor from the countryside as encouraged by the state. However, growing peasant resistance resulted in the coercion and dislocation of millions of Soviet peasants from their villages to *kolkhozy* by Soviet authorities and party officials, thereby destroying communities and local ties. As collective farms began to produce huge quantities of grains, increasing government requisitions for the purposes of dumping the product abroad in exchange for the capital needed for investment in the industrial sector caused the system to become strained, as peasants had little to eat and thus were not willing or able to produce. The result was growing discontent among the peasants, resulting in increased hoarding for subsistence. Ultimately, collectivization resulted in the dislocation of millions of peasants from their home communities, starvation en masse in places such as the Ukraine, and the forced relocation of kulaks to the Gulag in

Siberia (where thousands died) without improving agricultural production for full domestic consumption.

Agricultural Technology and the Environment

A cursory look at early-twentieth-century agriculture suggests continuity with traditional patterns of high levels of farm employment and, outside the USSR, minimal shifts in land concentration. The long era of extensification—in which food production increased as a proportional result of more land being farmed—was, however, beginning to reach its limits, except in the tropics. In Europe, North America, and Japan, more intensive use of the land was accelerating. The traditional, often direct, relationship between the amount of land under cultivation and human population levels gave way to a new agricultural regime. Larger, more elaborate irrigation systems and chemical fertilizers combined in some areas with mechanization to boost crop yields to unprecedented levels. The detrimental environmental consequences of such new techniques were not fully experienced, much less fully understood, during this era. The experience of the Dust Bowl in the United States was an exception; billowing clouds of dust exposed the results of mechanized farming on the semiarid southern plains, where farmers left vast acreages of fallow land unprotected by shelterbelts and suffered the consequences during the sustained droughts of the 1930s.

Irrigation is the oldest known method for raising yields, and it took on impressive dimen-

INDUSTRIAL NITROGEN

The industrial production and application of nitrogen to field crops may have allowed for more twentieth-century population growth than any other agricultural advance. The Haber-Bosch process of extracting nitrogen from air by synthesizing ammonia and thereby allowing the mass production of nitrates revolutionized agriculture. Today's intensive farms rely on synthetic nitrogen for 60–80 percent of the nutrient. Unfortunately, about half of this applied nitrogen escapes to the atmosphere and groundwater before it can be taken up by plant tissues. Entering many terrestrial and marine ecosystems, nitrogen can curtail photosynthesis and cause eutrophication in shallow waters. In the long run, only the stabilization of human population growth and maintenance (or adoption) of grain-based diets over nitrogen-intensive meat-based diets will help curb the use of synthetic nitrogen.

—*Tamara Whited*

sions in the twentieth century beginning with the efforts of British engineers who completed low-level barrage dams such as the one on the Indus River in 1932. Through the benefit of the 66 sliding gates that allowed the level of Indus River water to conform to water levels in seven connecting canals, India became home to one-quarter of the world's irrigated land by 1940. By contrast, the United States led in the construction of high reinforced concrete dams. Boulder (later Hoover) Dam, completed in 1935, culminated the federal government's 1902 decision to finance dam building.

Tractors had been around for decades before most farmers could afford them. Rarely manageable on the smaller farm fields of Japan and Europe, the gasoline tractor gained popularity among American farmers after 1910 and among Canadian, Australian, British, and Soviet farmers in the 1930s. Stalin launched the collectivization of Soviet agriculture in 1928, and by 1940 over 500,000 tractors were operating across the immense Soviet farmland, a sixfold increase from 1932. Harvesting combines, available in the 1920s, became agents of change as farmers began to adopt monocultures appropriate for

mechanical harvesting. Mechanized equipment eliminated the need for animal traction, which freed up cropland for human foods and eliminated manure that, in turn, further heightened the need for chemical fertilizers. At the same time, monocultures required pesticides and tailored the applications of chemical fertilizers.

With the twentieth century, scientists began to eclipse farmers in creating the conditions for bumper crops. The fields of agrochemistry and soil microbiology antedate 1900, and the three macronutrients—nitrogen, phosphorus, and potassium—were already known by the turn of the century. Chemists sought ways to synthesize these nutrients or at least extract them from treated rock (as with the production of superphosphate) or industrial wastes. The greatest breakthrough came with German chemist Fritz Haber's creation of usable nitrogen from synthesized ammonia, an achievement for which he won the Nobel Prize in Chemistry in 1918. Scientists were in turn stimulated to research micronutrients (iron, boron, manganese, zinc, and molybdenum), often depleted by massive use of industrial macronutrients.

The utilization of mechanized harvesting and the increase in chemical fertilizers also led to agriculture's thorough dependence on fossil fuels, and farmers were increasingly forced to select from a narrowing array of plant varieties that responded well to chemical treatments. Plant breeding, not surprisingly, followed the new dictates: the advances in crossbreeding of the 1920s and 1930s to produce dwarf varieties of rice and wheat paved the way for the postwar Green Revolution.

As the advances in technology changed the agricultural patterns, the consequences of these changes were only starting to emerge. The disruption of the natural cycles of nitrogen, phosphorus, and potassium led in turn to water and soil pollution. After World War II, the new irrigation techniques worked in powerful concert with Green Revolution crops but also encouraged salinization. In addition, dams altered hydrology, invited the buildup of silt, and threatened fish populations, concerns that would be voiced in the postwar era as well.

Dust Bowl and the Americas

The Dust Bowl was a region on the western edge of the Great Plains of the United States composed of 100 million acres in the states of Colorado, Kansas, Nebraska, Oklahoma, and Texas that suffered from extreme drought and severe dust storms in the period from 1930 to 1939.

The immediate seeds of the Dust Bowl were sown during the 1920s, when above-average rainfall, commodity prices, and easy credit led many farmers to plow up the tough prairie grass to make room for their crops. When drought struck in 1930, the topsoil calcified and turned to dust in the subsequent summers of intense heat. Crops rotted in the fields, and livestock wasted away. With the crops and native vegetation gone, there was nothing to hold the topsoil to the ground. While the drought was a global phenomenon, with its effects felt in East Asia, South America, and sub-Saharan Africa, the Dust Bowl was an event unique to the United States.

The first dust storm struck on September 14, 1930. Unlike the small dust storms that were traditional on the Great Plains, this storm was regional in size and covered hundreds of miles. The largest and most violent dust storm took place on April 14, 1935, and earned the nickname "Black Sunday," as it lifted and dumped over 300,000 tons of soil on the region. The dust storms of the 1930s were massive rolling black storms that broke windows, knocked men over, generated enough static electricity to short out an automobile, and coated everything in dust. The stronger storms had such intensity that they carried dust to the eastern seaboard and even deposited a layer on ships traveling the Atlantic Ocean.

► CHRONOLOGY OF IMPORTANT EVENTS LEADING UP TO THE DUST BOWL OF THE 1930s

1862—The Homestead Act was passed, and the U.S. government offered 160-acre parcels of land at very low cost in an effort to settle the west.

1878—John Wesley Powell reported to Congress that much of the trans-Mississippi West was too arid for farming. He suggested that the traditional 160-acre plots be abandoned in favor of communal farms or ranches that were larger than 2,000 acres.

1887–1888—Severe drought followed by a massive blizzard forced many ranchers to abandon their land. This led to the creation of more farms.

1902—The Newlands Reclamation Act was passed, creating a fund from which the federal government subsidized irrigation projects.

1914–1918—World War I created a spike in commodity prices that encouraged even more farming in the West.

1927—The great Mississippi River flood led to shortages of grain and induced even more planting on the Great Plains.

1930—Drought and the first dust storms usher in the Dust Bowl.

—Gregory J. Dehler

Storms paralyzed entire communities as businesses shut down and schools dismissed children. Dust and dirt blew into buildings through any crevice and covered the interior, including furniture, walls, pictures, books, and food. It was impossible to avoid breathing in the dust, and the worst cases led to debilitating respiratory ailments.

The economic toll was severe. The drought and storms prevented the Dust Bowl farmers from making payments on loans and mortgages, precipitating a total regional economic collapse. By 1938, living in such environmental and economic conditions caused the majority of the Dust Bowl families to seek some form of public assistance. Most families, however, stayed in the area, and of the approximately 220,000 migrants to California in the 1930s, only 16,000 were from the Dust Bowl itself.

An ardent conservationist and a believer in the progressive model of an activist government, President Franklin D. Roosevelt (1933–1945) dedicated federal agencies to combating the Dust Bowl. The Agriculture Adjustment Act of 1933 provided subsidies to farmers to leave fields fallow, thus removing the incentive to plow every available acre. Created in 1933, the Soil Erosion Service (renamed the Soil Conservation Service in 1935) led the federal effort against the

Dust Bowl. Working with the states, they formulated plans for shelterbelts of trees and furrowed soil contours to alleviate the wind and soil erosion that caused the dust storms. The young men of the Civilian Conservation Corps supplied the labor for this ambitious project, dubbed “Operation Dust Bowl.” The Soil Conservation Service worked closely with Department of Agriculture experimental stations in developing drought-resistant crops and more drought-sustainable farming techniques. Scientists from Africa, Australia, South America, and Europe traveled to the Dust Bowl to observe the operations and report back to their own countries.

The conditions began to improve when rain returned in 1938, although large and severe dust storms persisted for the next year and a half. In the fall of 1939, significant regionwide rainfall ended the drought and the Dust Bowl.

■ Introduction: Industrialization and Natural Resources

Industrialization, which continued at a rapid pace throughout the period from 1900 to 1945, had an obvious deleterious impact on natural resources. Land, water, and air were all polluted from coal-fired factories, steel foundries, railroad engines, automobile exhaust (including lead additives to petroleum), mining operations, deforestation, and chemical runoff from large-scale farming operations. While concerns over the overall “ecological” health of ecosystems were not common and such a vocabulary did not circulate at large except in the growing specialized field of ecologists, concerns for public health did arise, often focused on providing clean drinking water untainted by sewage or industrial discharge as well as some efforts focused on smoke abatement. The wilderness preservation movement had been gathering momentum since the late nineteenth century as wilderness and wildlife enthusiasts observed the effects of deforestation and mining, including erosion and the poisoning of pristine streams with mercury and other chemicals. Although logging operations slowed in the northern temperate zone during the first half of the twentieth century, deforestation continued unabated in the tropics as the region’s populations grew and demand mounted for new agricultural land and for the commodity of tropical wood, such as teak.

—*Fred Nadis*

Industrial and Water Pollution

In 1900 industrial pollution was not yet a global phenomenon, although in the 200 years between industrialization and the end of World War II, the ecological damage caused by those industrial waste products that tend to spread globally, such as carbon dioxide, increased three-digit percentages in certain parts of the world.

In most nations, even in the comparatively early industrial regions of Europe and North America, the immediately visible industrial pol-

lution was mainly concentrated in conurbations or special centers of production. More specifically, these were areas that offered raw materials such as iron, coal, and paraffin oil and areas that provided access to technologies or to chemical or mechanical production like Detroit (United States) and the Ruhr (Germany). Early industrial pollution affected large cities with rapidly increasing populations who were forced to live under severe health conditions. As a result of the early exploitation of the key raw materials, northern Europe (particularly Britain) and eastern North America suffered from pollution relatively early, while the changes of environmental circumstances in larger parts of Asia (except for some regions in East Asia), Africa, and Latin America were still primarily caused by agrarian and other means of production not associated with modernization.

Agrarian, commercial, and municipal sewage caused the main pollution of water cycles in many places until well into the twentieth century. In the areas surrounding the industrial centers, water, air, and ground pollution reached such a disastrous level at the close of the nineteenth century that more and more voices were calling for official intervention to protect the environment, such as establishing emission controls. However, for decades a lack of turning ideas into action predominated. Around 1900, some experts in industrial mining determined the content of salt in industrial sewage by tasting the water, which of course did not lead to reliable results. Moreover, critical studies of industrialization describe a withdrawal from a so-called moral economy toward an unscrupulous exploitation that many claimed to be typical during this period of industrialization in the Western Hemisphere.

Increasingly critical voices from several academic fields started to protest against unrestricted consumption of resources and excessive industrial pollution. These protests were sometimes followed by the establishment of corresponding special institutions such as the Pennsylvania Water Board, which tried to carry through a standardization in dealing with raw sewage. In 1925, Alice Hamilton wrote her rele-

vant study on industrial poisons in the United States; however, the different ways to purify sewage were still very controversially discussed among experts. At the same time, evidence illustrates that in regions where filtration systems were already in use, the rate of waterborne diseases decreased notably.

In addition to water pollution, it was generally industrial air pollution that harmed the quality of the environment in the United States and Europe in the years immediately before and after World War I. In addition, people had to deal with consequential emissions of harmful substances into the ecological system on a large scale as well as local noise pollution. Measures of relief, such as the extension of the sewage infrastructure, did not take place in the United States until the New Deal. At the same time, inhabitants in the Ruhr area in Germany—the largest industrial area of the world at the time—who complained about air pollution were told that measures against exhaust-gas pollution were simply too expensive. A special kind of pragmatism suggested to the inhabitants of the affected areas that they should instead adapt to the facts as they were and therefore cultivate only extremely robust plants, for instance.

In cities that were characteristically surrounded by an agrarian countryside, an argument rich in tradition took place between health authorities and farmers' representatives that continued until the early twentieth century. For example, in 1912 most of the supervisors responsible for the health of the population in the United States disapproved of sewage farming, a system in which sewage was not disposed or filtered but was used as fertilizer for the fields. Instead, these health authorities emphasized the dangers of sewage discharges into the water cycle. Nevertheless, even after 1930, cities were registered in more than a dozen states of the western part of the United States in whose rural surroundings sewage farming was still in practice.

During the first half of the twentieth century, both the possibilities for the disposal and the reprocessing of sewage in the Western industrial nations and the public and official sensitivity with regard to the still-growing problem developed considerably. Despite such progress, which varied considerably from place to place,

➤ AIR POLLUTION

Air pollution, in contemporary consciousness, is generally associated with the exhaust produced by traffic and factory smokestacks. The era of automobile use on a massive scale started about 1920, while factories blew their smoke into the atmosphere of Europe without having to comply with minimum standards for filtering the exhaust gases. The oil industry has also affected the environment to a considerable degree, having greater impact on certain local areas. For example, at the beginning of the twentieth century, oil refineries in cooperation with the steel industry were occupying whole districts of Hamilton in Canada to such an extent that a well-ordered town planning became absolutely necessary to avoid the increasing collapse of the socially and ecologically pressured seaside town. During the first decades of the twentieth century, many community planners perceived a different issue as the even bigger problem: the smoke of the trains that mainly transported travelers and industrial goods. Accordingly, authorities that were created to handle the trains' smoke were already in place by 1910 in some towns. In some industrial cities, such as Pittsburgh, certain smoke emissions were tolerated only for several minutes per day around 1940, given their high volume and the concentration of multiple industries in one conurbation.

—Lutz Hengst

an extensive and effective limitation of increasingly global industrial pollution remained a distant wishful goal of environmental activists.

Industrial Landscapes—Rapid Industrialization in the Soviet Union and Its Impact on the Environment

In the interwar Soviet Union, Marxist-Leninist ideology interpreted the natural environment as something to be conquered and tamed for the benefit of reaping rewards for socialist society under the aegis of the Soviet state. As part of the Second Five-Year Plan, the Soviet state under the leadership of Josef Stalin planned for the rapid development and expansion of heavy industry in the Soviet Union in tandem with the establishment of large state-run collectivized farms. As part of this pursuit of rapid industrialization, the state encouraged the relocation of millions of Soviet citizens into the Urals region in order to develop industrial cities in regions not vulnerable to a feared European invasion. As a result, vast new regions were opened for Soviet industrial and infrastructural development in the Urals, Siberia, and the Russian Far East. However, many of these newly opened regions were severely damaged: their environments suffered immensely as a result of the rapid rate of industrialization.

As the Soviet industrialization drive encouraged massive development in the Urals, Siberia,

and the Arctic regions, it also contributed to the rapid reshaping of the Soviet landscape. Previously undeveloped lands, which had remained untouched even late in the days of the tsarist regime, were lastly brought into development for the purpose of “building socialism.” Immense industrial complexes, such as the Ural city of Magnitogorsk, created new urban centers around large resource-extraction regions and mining centers. The result of these ventures was the large-scale development of huge, often highly polluting, factory towns fraught with air and chemical pollutants. Large-scale infrastructural projects, such as the irrigation canals diverting water from the Aral Sea to Soviet Central Asia, created the potentially huge ecological disasters in pursuit of water sources for large agricultural areas. Furthermore, such projects used forced labor from the Gulag (Chief Administration of Corrective Labor Camps and Colonies), often without the use of mechanical tools, and forced laborers to use manual labor for large-scale projects, such as the almost useless White Sea–Baltic Sea Canal. Such projects not only diverted state resources but also led to the destruction of natural habitats.

Much of the industrial development in the Soviet Union made prior to World War II resulted in the massive expansion of the socialist state in relation to much of the capitalist West, currently fraught with the effects of the Great Depression. However, much of this rapid development was done at the expense of the untapped natural resources of the Russian landscape. In terms of Marxist-Leninist ideology, the environment was merely something to be exploited and used for the benefit of industrial and economic expansion, not to be conserved for the purpose of ensuring the prosperity of future generations. As a result of this ideology, the Soviet Union continued many of these destructive policies throughout much of the history of their state, creating gigantic polluting industrial complexes, diverting rivers at the expense of maintaining fragile water ecosystems, and experimenting with nuclear and biological weapons, all the while polluting their once pristine natural environment and landscapes.

—Abraham O. Mendoza

► WHITE SEA-BALTIC SEA CANAL

The White Sea–Baltic Sea Canal, or *Belomorkanal*, was a ship canal constructed by convict-slave labor during the First Five-Year Plan, specifically from 1931 to 1933. The canal was constructed as a way to connect the Baltic Sea with the White Sea by connecting Lake Onega and Lake Vygozero by digging shipping lanes. Much of the work was done by human labor rather than by modern digging equipment, many of them “class enemies” being reeducated through work. Freezing temperature, deplorable working conditions, and brutality on the part of the NVKD (People’s Commissariat for Internal Affairs) led to an estimated 10,000 deaths. The end result was a shallow canal that could not accommodate the majority of shipping vessels and therefore remained essentially useless.

Deforestation

Deforestation, the removal of forest cover so thoroughly as to inhibit regeneration, was one of the most significant ways in which human beings transformed earth's surface in the years between 1900 and 1945. Human population growth accelerated during this period, yet we cannot establish a simple causal relationship between that growth and deforestation. Population growth, the expansion of both peasant and plantation agriculture, and the developed world's growing demand for tropical hardwoods were all factors that drastically reduced forest cover in the first half of the twentieth century. During this period, forest clearance in the tropical zones surpassed that in the temperate zones, reversing the pattern in place over the preceding two centuries.

In the North Temperate Zone (from 23.5 degrees north latitude to 66.5 degrees north latitude), a forest transition from net loss to net gain of forest was under way, though hardly visible, in 1900. This transition followed the steady deforestation in Europe and North America that was evident by the late eighteenth century. In the United States, wasteful logging and cutting for fuel and farmland had reduced the pre-Columbian forest by approximately half. Wood also had novel purposes such as pulp, packaging, and plywood; its use would not peak in the United States until 1907. The production of railroad ties in the developed world alone reportedly accounted for the destruction of more than 2 million hectares (approximately 5 million acres) of forest per year between 1888 and 1915.

By the end of the nineteenth century predictions of timber famine and its dire consequences had become common. Yet several transitions acted in concert to first stabilize forest loss then

> DEFORESTATION, 1900–1945

- 1900—Amount of forest cut for railroad ties peaks at 8.4 million acres (3.4 million hectares).
- 1900–1914—The United States doubles its imports of tropical woods for cabinetwork.
- 1914–1918—World War I creates high demand for wood for railroads, barracks, artillery shelters, and trenches.
- 1917—Chainsaws first manufactured.
- 1920 on—Eastern woodlands of North America are in full comeback, and total forest cover stabilizes.
- 1920–1949—The rate of forest clearance in the tropics accelerates from 7.4 million acres (3 million hectares) per year between 1850 and 1919, to 28.5 million acres (11.5 hectares) per year.
- 1923—Russian-born Raphael Zon's *The Forest Resources of the World* identifies population growth in the tropics as a growing cause of deforestation.
- 1928—Centralized planning in Stalin's Soviet Union ushers in forest mismanagement.
- 1929—The Great Depression causes international trade in wood to drop.
- 1935 on—Use of wood for fuel declines rapidly in North America.

—Tamara White

actually expand forest cover. These include the demographic transition, that is, the transition to low birth and death rates that helped stabilize population growth, along with rapid urbanization, abandonment of less productive farmland, substitution of new energy sources for wood, and the growth of scientific forestry. Meanwhile, developed countries began to import tropical wood and agricultural products on a greater scale, shifting the stress to tropical environments.

Growing population was also a major factor in the deforestation of the tropics. More than half a billion people were added to this area between 1900 and 1950. The accompanying demand for food played a major role in the removal of forest cover in two ways: first, forested land constituted the remaining areas capable of conversion to farmland, and second, carving farmland from forest provided a windfall of forest products, which

often stimulated further cutting. It is estimated that 235 million hectares (nearly 600 million acres) of tropical forest were cleared between 1920 and 1950, more than 70 percent of it for farmland with the rest transformed into grassland for grazing.

The increasing commercialization of tropical peasant agriculture was even more significant to the destruction of forests. According to John F. Richards and Richard P. Tucker in *World Deforestation in the Twentieth Century* (1988), population growth transformed tropical forests less than First World demand for both timber and agricultural products. Western imperialism, whether formal or economic, led to the development of tea plantations in Assam, India; cotton and peanut production in the African savannas; and sugar and coffee farming in coastal Brazil. All of this was at the expense of forest land. Demand for teak in Western markets reached a prewar peak in 1913, and Western governments facilitated the extraction of tropical timber by building or upgrading railroads and ports.

The two world wars and the Great Depression temporarily slowed the flow of tropical woods, but the belligerent nations needed much wood and traded with allies or neutral countries to obtain it. Timber in occupied tropical regions, such as the Philippines during World War II, quickly became war matériel. Forests were obliterated in war-torn zones of France and Germany, yet most damage proved temporary. A more significant outcome of the wars for temperate zone forests was the trend toward even-aged, single-species forests managed with pesticides and fertilizers. This trend led to the globalization of fast-growing, resistant tree species, such as the American Lodgepole pine. These managed forests contrasted with the tropical forests that continued to be felled for farmland or for cash.

Impact of Fossil Fuel Extraction and Use

The environmental impact of fossil fuel use and extraction in the period between 1900 and 1945 included deforestation, air pollution, water pollution, and widespread contamination by lead and other toxic substances. In addition to the environmental consequences, there were also health and safety implications of fossil fuel extraction and production.

In the twentieth century coal, petroleum, and natural gas powered private homes, vast industrial complexes, and transportation. Of the three, coal was the most widely used in 1900, while petroleum was mainly distilled into kerosene to provide lighting in private homes. For the most part, natural gas was rarely used before 1945.

Coal dust coated many populated areas in the world with soot and grime. At times, coal dust made the air so dark that day looked like night. London, England, Pittsburgh, Pennsylvania, Osaka, Japan, and the Ruhr region of Germany were notorious for pollution by coal-powered industry. Coal pollution blocks vitamin D from the sun, leading to widespread disease such as rickets. Lung ailments, including tuberculosis, bronchitis, and pneumonia were also common and often fatal illnesses caused or worsened by smoke pollution.

Before 1950, only in the United States and some parts of continental Europe did electricity replace coal as the main source of power for homes. Even so, coal-fired power plants supplied most of the electricity and produced sulfur dioxide and nitrogen oxide leading to acid rain, which polluted waterways and soil. To obtain coal, mining operations left lasting scars on the land, including fouled waterways, deforestation, soil erosion, and contamination from toxic substances.

The internal combustion engine created great demand for gasoline, which by 1910 had replaced kerosene as the leading petroleum product. In 1921 lead was added to gasoline in order to improve engine performance, thereby causing engines to discharge the toxin through exhaust fumes. Lead does not break down and accumulates over time. Furthermore, in cities especially in the United States, gasoline-powered

THE BREAKER BOYS

Coal mining was dangerous and dirty work. Boys as young as eight began a life in the mines working as breaker boys, sorting coal from other rocks as the material came down chutes. Typically breaker boys were poorly paid, lacked protective clothing such as gloves or face masks, and worked long hours. Many breaker boys went on to become miners as they got older. Long-term exposure to coal dust led to a crippling condition known as black lung that took the lives of many who worked in the coal mines.

—Gregory J. Dehler

Young coal miners enveloped in a cloud of coal dust in a Pennsylvania mine, 1911. (Library of Congress)

buses replaced electric trolleys as the mainstay of mass transit, increasing exhaust emission levels. Demand for tires led to forest clearing in Southeast Asia, as trees were felled to make way for rubber plantations. Competition to control some of the world's most productive oil fields, especially in the Middle East and Southeast Asia, helped to cause wars.

The demands of two world wars, industrialization, and new modes of travel led nations to continue to aggressively seek new sources of fossil fuels. New technologies, such as better drills, aerial photography, and seismography, allowed more oil fields to be opened. To get at the oil and clear the way for pipes, forests were cut down. When petroleum prices dropped, as they did in the early years of the unstable oil market, it was common for operators to pump the crude directly into nearby rivers instead of shutting down the wells. As a result, rivers, harbors, and wetlands became saturated with clumps of petroleum. There were also oil spills during transportation. In addition, oil refineries that broke down the crude petroleum into gasoline contributed markedly to air and water pollution through the refining process.

Some attempts were made, however, to moderate the ill effects of fossil fuels. Smoke-abatement programs were common in the United States,

England, and western Europe, and occasionally they had some local success by calling attention to the need for more efficient stoves and power plants. In the early 1920s the United States and Great Britain enacted regulations to limit the dumping of petroleum in waterways, although when the United States hosted an international convention (1926) to discuss limiting the amount of petroleum dumped in the ocean, it had minimal success.

The extraction of fossil fuels from the turn of the century until the end of World War II posed an ever-present threat to ecosystems throughout the world, leading to a heightened awareness of the need to regulate the negative environmental impact of fossil-fuel exploration and use.

■ Introduction: Societal Responses to Environmental Pressures

World recognition of the importance of the environment can be dated to the Renaissance. The rebirth of knowledge and the beginning of a steady increase in the world's population caused many to think about the role of nature in the world. Not until the nineteenth century, however, were real efforts made to protect and preserve the environment, and actions did not take place on a global scale until almost a century later.

In the United States, environmental concern came to the forefront of national attention after the release of the 1890 U.S. Census Bureau report, which declared that after centuries of settlement and development, the U.S. frontier had officially disappeared. The announcement came as a shock to many Americans, who had long viewed the country's land and natural resources as inexhaustible. Public concern about an impending resource famine sparked the formation of government agencies to regulate and conserve the nation's remaining land, wood, and water and preserve wild land in a completely undeveloped form.

Despite the establishment of the U.S. Forest Service and the U.S. National Park Service, neither conservation nor preservation remained high priorities in the United States. In fact, the 1920s saw unprecedented economic growth and urbanization, with little regard for the environment. The stock market crash of 1929 then ushered in the era of the Great Depression and U.S. president Franklin D. Roosevelt's New Deal legislation, which funded huge public works projects that helped the nation recover from the depression but often damaged the environment. In addition, the drought of the Dust Bowl, which devastated large portions of the midwest and south in the 1930s, highlighted the toll that sustained farming took on the land. European environmental movements during the twentieth century reflected the American experiences. Acid rain heavily affected the industrialized Ruhr region in Germany, and the spread of the automobile caused the growth

of road networks and air pollution, which led to such environmental responses as *Britain and the Beast* (1937), written by John Maynard Keynes.

World War II left a legacy of environmental consequences around the world, and concern over chemical pollution and the dangers of radiation were noted in many countries. The rapid development of industry came with a severe environmental cost: the contamination of water, air, and soil with a new generation of nonbiodegradable toxic materials. The cause of environmentalism entered the mainstream as one of many issues during the 1960s that prompted activism.

—Timothy J. Watts

Conservation and Preservation

In the early twentieth century, a variety of private clubs, leisure groups, individual landowners, and scientific organizations around the world successfully persuaded their governments to establish national conservation and preservation policies managed by trained professionals working out of government bureaucratic institutions. While conservation placed its emphasis on managed use and measured the value of natural resources mainly in economic terms, preservation focused on the aesthetic, moral, and emotional benefits of nature.

By 1900, Russia had created large forest reserves; Australia, Canada, Mexico, New Zealand, and South Africa had established national parks; and the United States had established both forest reserves and national parks. In the first decade of the twentieth century, President Theodore Roosevelt (1901–1909) advanced the United States far ahead of other countries in the implementation of conservation policies, primarily through the creation of bird and big game refuges, the expansion of the national forest system, federally funded reclamation, the establishment of the National Forest Service (a national

resource inventory), the National Monuments Act (which allowed for the protection of such scenic wonders as the Grand Canyon), and additions to the national park system. Roosevelt cast conservation as a democratic movement to reclaim the benefits of the natural wealth for the good of the many over the profit of the few.

Between 1910 and 1930, other nations followed the example of the United States. Several countries, including Argentina, Chile, Japan, Italy, Sweden, Switzerland, and the German state of Prussia, established national parks. Unlike the United States where national parks functioned mainly for recreation, European governments used national parks to test, practice, and showcase conservation regulations and good scientific practices.

The Great Depression and the growing nationalist movements of the 1930s combined to push conservation to the forefront of public policies. President Franklin D. Roosevelt gave conservation a prominent place in his New Deal program, which included the Civilian Conservation Corps, regional development plans, and soil conservation. Germany adopted many advanced conservation policies and became the first European nation to establish nature preserves. Brazil enacted its first conservation laws, national parks, forest codes, and the like during the 1930s. In scale, however, the United States vastly exceeded the efforts of other countries due to its greater territorial expanse. It would not be until after World War II that Britain, France, and many of the other European countries enacted conservation policies similar to Germany and the United States.

In terms of imperial management, European colonial powers implemented conservation in their overseas territories as a means to maximize profit from natural resources as well as control native populations by limiting their access to hunting, forests, and valuable agricultural lands. Through the India Forest Act (1878) and the Indian Irrigation Commission (1900), the British were able to effectively deprive Indians of the ability to use the forests for fuel or to farm on traditional lands. As a result, the population was increasingly encouraged to farm on submarginal land, which led to serious problems stemming from soil erosion in the 1930s. The Dutch in the East Indies, the French in Northwest Africa, the

➤ HETCH HETCHY CONTROVERSY

Although conservationists and preservationists joined forces against the despoilers of nature, they could become embroiled in bitter conflict among themselves. After the devastating earthquake of 1906, the city of San Francisco demanded another water reservoir. In 1908, the U.S. government approved construction of a dam in the Hetch Hetchy Valley of Yosemite National Park. John Muir rallied preservationists across the nation in opposition to the project. He argued that national parks, once created, were inviolate natural sanctuaries. Muir also spoke eloquently on the unique beauty of Hetch Hetchy Valley. Conservationist supporters of the dam project, on the other hand, argued that human needs came before nature and even claimed that an artificial lake in Hetch Hetchy would vastly improve the aesthetic qualities of the valley. Despite the spirited opposition of the preservationists, the law to dam Hetch Hetchy passed both houses of Congress and received presidential approval in 1913.

—Gregory J. Dehler

Germans in East Africa, and the Belgians in the Congo all followed similar imperial conservation policies. In 1940, Britain enacted a comprehensive conservation policy for its empire, but World War II delayed its implementation.

Conservation often transcended national boundaries. In 1900 and 1933, Britain hosted conferences devoted to African conservation, which led to the adoption of several policies that all colonial powers uniformly practiced. It should be noted, however, that Africa was not the only continent affected by conservation diplomacy. In the early twentieth century, fur seals, migratory birds, and oceanic fish stocks were regulated by international treaties and subjected to conservation controls. Between 1900 and 1945, several international conferences addressing conservation were held around the world.

Development of Ecology as Discipline and Impact on Political Thought

The field of ecology emerged slowly in the last quarter of the nineteenth century. The term "ecology" was first used in 1866 by German biologist Ernest Haeckel to describe the interaction between the various scientific disciplines and the environment. However, it was English naturalist Charles Darwin who inspired the growth of the field by depicting nature as a

space where interconnected species conflicted and interacted with each other and their environments on a continuous basis. Some of the earliest ecological studies, such as Stephen Forbes's lake studies in the 1880s and Henry Cowles's sand dune studies in the 1890s, were direct inquiries into the ecological mechanics of Darwinian nature. Most of the contributions to the development of ecology between 1900 and 1945 originated in Britain and the United States.

During most of the period between 1900 and 1945 two rival explanatory models polarized ecologists. American botanist Frederic Clements argued that an orderly and systematic nature in which large plant communities formed, grew, climaxed, and declined and were replaced by new plant communities better adapted to the environment represented the norm. Henry Gleason of the New York Botanical Garden, on the other hand, argued that nature represented less the formation of recognizable, stable communities and more the struggle of individuals against their environment. Both men inspired many followers and students, who took this argument into their field research in attempts to prove their case. Partisans of the two schools of thought could be found on both sides of the Atlantic dividing academic meetings, faculty discussions, and professional organizations, including the British Ecological Society (1913) and the Ecological Society of America (1915).

During the mid-1930s, several important ecologists expanded the discussion beyond Clements's and Gleason's dichotomy of community formation versus individual adaptation. Seeking a new unit of measurement to accommodate Clements's unwieldy and ill-defined plant community, Arthur Tansley, a British botanist, first applied the term "ecosystem" to scientific studies. Tansley further distanced himself from Clements by arguing that there was no one single model of plant community succession. American zoologist Charles Elton and South African ecologist G. Evelyn Hutchinson, who worked out of Yale University, introduced the concepts of energy flow and ecosystem metabolism through the food chain into debates on ecology. This had an important implication because the U.S. government was spending millions of dollars every year killing predators, such as wolves,

» ELLEN SWALLOW RICHARDS

"What touches my neighbor, touches me," wrote pioneer ecologist Ellen Swallow Richards (1842–1911) in *Sanitation in Daily Life*, published in 1907. This quote captures her view that humans interacted with both their environment and each other in the modern, industrial, urban society. Whereas Frederic Clements, Henry Gleason, and most of the men of the first generation of ecologists focused their attention on plant formations, Richards was concerned about endemic pollution, stunted children, rising disease rates, and malnutrition. She devoted herself to the causes of cleaner living, better food preparation, improved sanitation, and sewage disposal, all in the name of promoting a greater individual responsibility for the shared environment. Richards taught at Massachusetts Institute of Technology, where she had earned her degree, for over 30 years, held classes outside the academic setting, and wrote several books and articles in an effort to convince others to follow her standards of ecological living.

—Gregory J. Dehler

on federal lands. By arguing that there was a metabolism or food chain, Elton and Hutchinson gave an ecological value to predators. A community missing one part of the food chain was a broken community. By the end of the decade, the U.S. government ceased killing predators in national parks lands, although the extermination program continued on other lands that were also leased for livestock grazing. In *Game Management* (1933), Aldo Leopold of the University of Wisconsin provided practical measures to establish wildlife-friendly habitats in order to restore animal populations to both large and small areas. Any unit of government, indeed any landowner, could use this book to provide a more ecologically sound habitat for deer, turkey, birds, and other species. Over the nearly two decades between *Game Management* and his death in 1949, Leopold carried this concept of ecology forward to include the principle of biotic citizenship in which all species are equal members.

Ecology moved out of the university and into the realm of public policy in a dramatic fashion during the Great Depression. The Dust Bowl, an extreme example of human mismanagement of land, touched four states in the U.S. Great Plains. Years of damaging and exploitative farming techniques created the first environmental catastrophe since the formation of ecology as a science. Ecologists took the lead in offering solutions to federal agencies and encouraged the planting of trees for a shelterbelt, the practice of better soil conservation and irrigation methods, and the improvement of individual land management through the Agricultural Adjustment Acts. In addition, President Franklin D. Roosevelt employed ecologists to design the Tennessee Valley Authority regional development plan.

One offshoot of ecology applied the principles to urban planning. Patrick Geddes of Scotland thought that large sprawling metropolises were culturally and ecologically unsustainable. In the 1920s, Geddes designed model villages in accordance with ecological concepts. In the following decades, one of his disciples, Lewis Mumford of the United States, applied similar planning models to larger urban communities.

In 1942 Raymond Lindeman wrote a paper synthesizing scientific developments in the field of ecology. The 27-year-old scientist added his

own theories to those already established by Clements, Elton, Hutchinson, and Tansley. Lindeman's resulting work revolutionized the conceptualization of the ecosystem and set ecology on a new course for the postwar period.

Water Management in the Americas

Across the globe, water management practices changed significantly during the first half of the twentieth century. The construction of large dams, dams over 49 feet (15 meters) high, is one of the most visible symbols of this change. As engineers began to better understand the science behind dams, construction techniques changed and improved, leading to larger structures, the creation of multipurpose projects, and more federal intervention including increased regulation and standardization. These changes in water management practices, especially mounting federal involvement and peoples' increasing ability and willingness to transport water over large distances, allowed for the growth of large cities, lush suburbs, and irrigated farms regardless of the natural environment.

The first half of the twentieth century marked a general shift in population density in the Americas. Between 1920 and 1940, the urban population in the United States increased from 54.2 million to 74.4 million, and similar patterns occurred in South America. Rural life became less attractive as industrial growth expanded, creating new opportunities in the rapidly growing cities. But these exploding urban areas required a larger water supply for homes and industry, and growing populations worldwide

➤ HOOVER DAM—THE “GREAT PYRAMID OF THE AMERICAN DESERT”

The Hoover Dam, dedicated in 1935, marks the beginning of federally funded, large-scale, multi-purpose water development projects in the United States. Originally named the Boulder Dam, the arch gravity dam built across the lower Colorado River, about 25 miles southeast of Las Vegas, impounds two years of the river’s average flow. Constructed under the aegis of the Reclamation Service (today’s Bureau of Reclamation), the dam stands 726 feet high, at the time making it the largest dam in the world by almost 300 feet. As a multipurpose project, the dam provides hydroelectric power, water for irrigation and urban use, and protection against flooding.

The dam became an important symbol of American ingenuity, technological prowess, and the ability to harness nature during the Great Depression. In addition, it also provided thousands of temporary jobs at a crucial time in American history. Though the labor was dangerous and conditions were harsh, with summer temperatures soaring to well over 100 degrees, workers and their families flocked to the inhospitable desert canyon from across the nation looking for employment in a faltering economy.

Boosters accurately labeled water as the factor limiting expansion in the Southwest, and the dam acted to stimulate economic growth throughout the region. Today, Colorado River water supports communities across the Southwest, providing water and hydroelectric power that allows Southwestern cities to grow beyond what local resources can support.

—*Eliza Layne Martin*

necessitated the expansion of irrigated acreage for food crops. Likewise, the continued westward migration of Americans into the arid and semiarid regions acted to heighten the pressures on local water supplies. To support and drive forward development, water needed to be imported into these growing arid areas.

The politics of water management matured in this period as federal governments became increasingly involved in water development. In the United States, the creation of the Bureau of Reclamation in 1902 marked a turning point,

placing the federal government in charge of massive irrigation projects. Up to this point, irrigation had primarily been funded by individuals, private companies, and municipalities. New methods of mixing and pouring concrete during the first half of the twentieth century impacted dam development and water management, making both larger and more structurally complex edifices possible. Yet these projects’ scope and expense made it difficult for smaller bodies or private entities to fund them.

With federal involvement we start to see the first multipurpose dams, meaning dams that are built to serve more than one function. Proponents of multipurpose dams promised that their hydraulic projects would bring water for irrigation and growing cities, protect from floods, and produce hydroelectricity to drive forward a growing economy. Though some of these aims are at odds with one another—for instance, to protect from floods you want a dam’s reservoir to be empty, while to produce hydroelectricity you want it as full as possible—dams promised to tame nature for human needs and to allow deserts to flower and cities to blossom.

One of the most famous early multipurpose projects is the Hoover Dam, built across the Colorado River in the 1930s. Modern hydraulic engineering arguably began with Hoover. As the world’s first superdam, Hoover stood as a symbol of Franklin D. Roosevelt’s New Deal and the promise of American technological prowess. Next came the Grand Coulee on the Columbia River, to be followed by a slew of multipurpose high dams across the world, each taller and more impressive than the last. Many of these dams were important as symbols of modernism, economic development, and human control over an unpredictable natural world. Though the majority of U.S. government-sponsored projects were in the trans-Mississippi West, the Tennessee Valley Authority is a prime example of multipurpose water development in the East during this period. Meanwhile, engineers built similar large-scale projects around the globe, such as the Guarapiranga Reservoir in Brazil.

Just like North America, South American countries such as Brazil aimed to increase industrial growth and agricultural output. To do this, they turned to electricity and irrigation. Lacking

in coal, the fuel of choice at the time, though rich in running water, hydroelectric seemed an obvious solution to Brazil's power needs. A significant spate of Brazilian dam building occurred during the early 1920s, yet much of the large dam development in South America did not take place until the second half of the twentieth century. While Brazil was one of the early leaders in water development on the continent, Argentina, in particular, has embraced large dam building since the 1970s.

Throughout this period, hydrological engineers, especially from western Europe and the United States, traveled across the globe helping to build dams in developing countries. Dam building played a special role in the imperial project; for example, dam building in many developing areas fostered an expansion of irrigated agriculture, leading to the growth of more cash crops. Imperial powers viewed these crops grown for the global market, especially cotton, as an important source of revenue for their empires.

Though these dams and their accompanying infrastructure provided many advantages and are awe-inspiring examples of human technical prowess, not everyone benefited from them. Large water projects can flood extensive areas, displacing entire communities. Access to irrigation also changes cropping patterns. In order to pay for the more expensive imported water, farmers tend to grow cash crops for export instead of traditional subsistence crops, drawing farmers more firmly into the world economy and making them more vulnerable to downturns in distant markets. Extensive water management also creates unintended environmental consequences. Dams make irrigated agriculture possible but threaten productive farmland by blocking the passage of silt and depositing salt in the fields, leaving the soil unsuitable for crops. Finally, dams can block fish from spawning and ruin wetland and riparian habitats.

Urbanization and Suburbanization

The explosion of cities from the mid-eighteenth century continued into the twentieth century. Trends begun in Europe spilled outward to the Americas and urban centers in Asia and Africa, where European trade links and cultural influence were significant. Industrialization affected ever more cities, drawing more and more people from rural areas whose agriculture was being transformed by the chemicals and machinery produced in urban and suburban plants, lessening the amount of labor necessary for farming. Transportation networks grew denser, first as trains and trams spread out from more and more city centers, linking satellite towns and villages to urban hubs and to each other and more urban hubs to one another. Diesel and electricity replaced horses and steam as sources of energy on urban and interurban routes, and by 1900 gasoline engines and the automobiles they powered were making their mark, increasing individual and family mobility for the middle and upper classes.

While rail lines had produced tendrils of development that snaked out of urban centers into the countryside, it took the automobile, with the independence of movement it provided, to open up wide swaths of exurban land to development. In American cities this often meant that existing rail lines went underused or were shut down, and often newly developing cities had little in the way of mass transit. This had the effect of stranding the less wealthy who worked in cities in rings around the industrialized or commercial city centers, while middle-class families could afford to move farther out. This suburbanization was fed by the relocation to cheaper land outside the center by lighter industries and service providers as well as retailers who served family

“Is it inevitable or basically sound or desirable that larger and larger crowds be brought into the city’s center; do we want to stimulate housing congestion along subway lines and develop an intensive rather than an extensive city; will rapid transit spread the population anywhere except along the new right of way; is it ultimately desirable to have an area of abnormally high land values with its consequent demand for the removal of building restrictions; must all large business, professional and financial operations be conducted in a restricted area; must the worker be transported through the heart of the city to get to work; as a matter of fact are not all of these assumptions, which were controlling in the past generation, being severely arraigned by thoughtful students? . . . [T]he city of the future ought to be an harmoniously developed community of local centers and garden cities in which the need for rapid transportation over long distances will be reduced to a minimum.”

—Joseph P. Byrne

needs. Older European cities and towns did little during the period to adapt to the automobile since it and its fuel remained luxury items. In Europe, newer development took place along or near existing or planned public transportation routes, creating generally high-density suburban use. American developments, on the other hand, needed little more than a single trunk road and low density; large-lot residential areas became a norm even around older cities.

As World War I drew millions of men from European countries, colonial lands, and the United States, there were internal migrations to the industrial centers where the belligerents and their allies produced their war matériel. Women also entered the urban workforce in large numbers, requiring housing and changing the social landscape of many cities. In the United States, many southern blacks were drawn northward to

industrial centers such as Detroit, Pittsburgh, and Chicago, changing the racial landscape of America’s urban industrial north in what would continue—especially during the Great Depression—as the Great Black Migration.

In the postwar 1920s, cities around the world increased in size and population densities as steel-frame high-rise structures replaced older forms of residential architecture. Subways and surface mass transit appeared in older centers like Moscow to carry people in and out of the central city. Dictatorships in countries such as the Soviet Union, Germany, Italy, and Japan used their resources to reshape their capitals and provide social efficiencies such as the Autobahn in Germany.

The Great Depression of the 1930s affected manufacturing and trade in cities throughout the world. The resulting unemployment drove many out of their urban homes and back to the countryside, while governments sought to provide for the destitute. Government programs, among which were rearmament and military recruitment in most countries, eventually helped stabilize urban flight. From the outset of World War II in 1939, belligerents targeted enemy cities with bombs, land forces, and even rockets. Urban centers throughout Europe and in China, Japan, and the Philippines were scarred or reduced to rubble, while cities in ancillary regions such as the Americas and Australia continued to grow in size and importance.

Health and Sanitation

In the United States and western Europe, the first half of the twentieth century saw some of the most basic problems of public health and sanitation largely solved through municipal ef-

forts, thus greatly improving the health of citizens in those countries. Foremost among these reforms were the development of municipal water and sewage systems, efforts that have proven so successful that potable water is an expectation in most industrialized countries. In addition, the concept of health as a public good and a basic level of health care as a human right became firmly established in much of the industrialized world. Unfortunately, these benefits are not universal: more than 1 billion people in the world lack access to safe drinking water, and an estimated 3 million people die from waterborne diseases worldwide each year. The access to minimal levels of health care varies widely not only between countries but also within many countries, depending primarily on an individual's ability to pay.

A number of breakthroughs in microbiology in the late nineteenth century, including the identification of the microorganisms responsible for cholera, typhoid fever, tuberculosis, and diphtheria, led to the acceptance of the germ theory of disease and to the increased interest in improving public health through sanitation. Much of this effort was focused on cities, because crowded living quarters provided the ideal conditions for the spread of communicable disease. In addition, in cities the rich and poor often come into contact with each other, and the proximity of rich and poor has meant that an epidemic that began in the slums could quickly spread to the wealthiest neighborhoods. Many cities established boards of health in the second half of the nineteenth century, starting with New York City in 1866. Even before there were effective treatments (such as antibiotics) for many infectious diseases, these boards of health helped contain disease outbreaks through inspections, immediate case reporting, and rapid investigation.

The new emphasis on sanitation represented a shift in philosophies on two fronts: the causes of illness were attributed to poor social and environmental conditions, and protecting public health became a societal rather than a private responsibility. Recently acquired knowledge about the causes of diseases also encouraged a shift to a more long-term view focused on preventing diseases rather than curing them. For instance, filtration of drinking water, a municipal process,

> LILLIAN D. WALD

Lillian D. Wald (1867–1940) was a pioneer public health nurse and social worker in New York City. She invented the concept of the public health visiting nurse and founded the Henry Street Visiting Nurse Service, which provided house calls to patients, many of them recent immigrants to the United States, living in tenements. Wald was also involved in many health-related social causes including improved tenement living conditions, fire safety in factories, and the abolition of child labor.

(Library of Congress)

—Sarah Boslaugh

in the early twentieth century greatly decreased the number of cases of typhoid fever, an individual consequence. In 1908, 35 American cities had death rates from typhoid of more than 15 per 100,000. After filtration systems were added to municipal water supplies, only three cities had rates that high.

State and city health departments also took on a number of other tasks to combat disease. One was the establishment of disease registries. A second was the establishment of public clinics that offered both education and health care, often focused on a particular disease (such as tuberculosis) or demographic group (such as children). A third was the establishment of visiting nurse services, which took health care to people in their homes, and led to further recognition of the connections between poverty, unsanitary living conditions, and disease.

Improvements in public health and sanitation came more slowly and unevenly outside the Western industrialized world. In fact, the sanitation revolution is only today reaching some parts of the developing world. However, some Asian countries were early adopters of sanitary

reforms. For instance, Tokyo constructed a municipal water supply in 1889 and a sewage treatment system in 1922. In other cases, sanitary improvements were instituted by colonial ruling powers, for instance in the British colonies of Singapore and Cape Town, South Africa. Such municipal improvements were sometimes a mixed blessing to the native population because they were often instituted primarily to benefit members of the colonial ruling class. Ruling elites also sometimes relied on sanitary reforms as a pretext to instill or reinforce racial segregation.

Brazilian Environmentalism

Between 1920 and 1940, the Brazilian political-intellectual scene was charged with intense nationalism and with an urge to modernize both social and political institutions. These themes influenced reflections about industrialization, political institutions, law, the arts, cultural heritage, and the protection of nature.

In the field of nature protection, a small group of scientists and intellectuals was devoted to the goal of saving the Brazilian natural heritage. They became the founders of Brazilian environmental awareness, although they are not duly acknowledged as such. Their impact is in part explained by the connections that they made between the protection of Brazilian nature and the construction of the nation's identity. They were scientists, but they argued politically that Brazil should attach its identity to its wealth of natural resources and landscapes, both for economic and aesthetic reasons.

The Museu Nacional do Rio de Janeiro (MNRJ), a museum specializing in natural history and anthropology, was the group's major institutional base.

Likewise, the First Brazilian Conference for Nature Protection, held in Rio in April 1934, was

a cradle of Brazilian environmentalism and a rallying point for these scientists and hundreds of other citizens interested in the matter. The event was promoted by several civic groups with MNRJ support. The annals of the meeting show that the bulk of the participants conceived nature as an organic entity involving all forms of life, including humans. Nature should be used but also admired and cared for as part of the Brazilian national identity. However, participants were aware that this notion had to be nurtured by public education at all levels so that citizens, particularly children, would learn about the importance and the beauty of animals, plants, and landscapes.

Large-scale tree plantations, composed of both native and exotic species, were suggested for commercial purposes, for the recovery of degraded lands, and for watershed protection. In addition to recommending that aesthetic landscaping be widely practiced to create nature gardens, the group promoted the idea that selected areas be set aside for preservation, aesthetic appreciation, and scientific research. At the same time wilderness, or unspoiled nature existing beyond frontier settlements, was defended for its own sake. Conference attendees, aware that the management of tropical forests still lacked a scientific basis, proposed research programs. Other conference recommendations were international cooperation in the area of nature protection, the selection of areas to be protected, environmental education, and more cautious use of natural resources.

The conference also reflected the concerns and stimulated the continuing activity of a group of MNRJ scientists: Alberto José Sampaio (1881–1946), chief botanist at the MNRJ and one of the most important Brazilian botanists of all time; Armando Magalhães Corrêa (1889–1944), sculptor, painter, writer, and self-taught naturalist and renowned sketch artist of plants, animals, and landscapes; Cândido de Mello Leitão (1886–1948), Brazil's leading zoologist and a professor at the museum; and Frederico Carlos Hoehne (1882–1959), a self-taught naturalist who became an expert in ecology, biogeography, and botany.

The 1934 outpouring of natural resource legislation, such as Brazil's first Forest Code, was largely shaped by Sampaio's findings, proposals,

and goals. He fought for the creation of a national forest service, which would deal with logging permits as well as require sustainable-yield use of forests and commercially planted forests. In addition, his biogeographical research helped in the selection of areas to be preserved. In general terms, Sampaio considered the wise use of natural resources to be compatible with respect and love for nature.

Corrêa, studying nature and humans in the rural outskirts of Rio de Janeiro in the late 1920s, brought the issue of the Brazilian open frontier (*sertão*) and its vast natural resources to the Brazilian urban elites. Less than 32 miles (50 km) from downtown Rio in the 1920s, he found people who lived off the land as fishermen, hunters, collectors, loggers, charcoal producers, and small farmers. He showed that the outback actually started close to the national capital. People living there were immersed in a fragile low-productivity, natural resource economy, apart from the realm of modern political and social rights, just as remote Amazonians lived at the time and still live today. Sometimes, he argued, these "forsaken" people helped conserve nature, but many other times their poverty made them destroy their own resource base. These people could remain, he thought, in touch with nature but must also be brought into the realm of citizenship, institutions, and the national state in order to lead a better life, one less dependent on nature.

Mello Leitão argued that there was a positive relation between investments in scientific research, appreciation of nature, and national consciousness. He was an evolutionist who considered cooperation to be more important than competition for the survival of individuals, populations, and species. On a different note, he considered biology to be a doorway into the secrets of nature and its revelations for all people. He was a harsh critic of short-term wasteful uses of the land and its resources.

Hoehne was an early defender of parks and preserves. He was concerned with faraway landscapes but was also an ardent defender of remnant forests inside the perimeter of the city of São Paulo. Not a strict preservationist, he favored the wise use of resources in a manner that could well be coupled with the notion of sustained

Cover of the annals of the First Brazilian Conference for Nature Protection, held in Rio de Janeiro in April 1934. yield. He argued, however, that in a broader sense there was a moral balance to be achieved between utility and aesthetics in human relations with nature. Humans should seek harmonic relations with nature, knowing and admiring it. In his extensive field trips to several parts of the Brazilian territory, he had a special eye for discriminating the parts of the land that should be used for production from other parts to be set aside for conservation and preservation. Hoehne's close relations with São Paulo politicians allowed him to exert some influence over conservative farmers and their farming practices. He was active also in the creation of the first Brazilian national parks. The São Paulo Botanical Gardens, created by Hoehne, became a model institution for research and education.

Writing from the 1920s to the 1940s, these scientists laid the foundations of a scientific conservation movement in Brazil. Although they also achieved some influence over natural resource policies, conservation did not become a mainstream concern of Brazilians during their careers. Much to the contrary, Brazilian political leaders, farmers, industrialists, and the general population believed above all, during most of the twentieth century, in development at all costs. Nonetheless, the findings and the proposals of these pioneering conservation scientists remain relevant to the present-day paradigm of

reconciling growth with environmental quality, as the belief in development at all costs lingers on in many segments of Brazilian society.

■ Introduction: Warfare, Population, and Environment

The moon crater landscape of the western front of World War I and the aftermath of the dropping of the atomic bomb on Hiroshima in Japan at the conclusion of World War II stand as two of the most extreme cases of the effect of warfare on the environment. From 1900 to 1945 the destructive impact of the two world wars on population and environment was monumental in terms of numbers and scale. In tandem with large-scale genocides, most notably the Holocaust, and political famines, such as the Ukrainian famine of 1932–1933, this period led to military and civilian deaths in the tens of millions. Moreover, the new nature of warfare, on a far more vast geographical scale and characterized by new technologies, allowed for the destruction of cities, ecosystems, and entire landscapes.

—Abraham O. Mendoza

Impact of War on the Environment

At the beginning of the twentieth century, warfare had become a prominent factor in global ecology. Rapid advancement of science and technology not only afforded developed states the ability to go to war for longer periods of time and at a greater distance, but the advent of chemical warfare and nuclear weaponry also al-

lowed them to inflict exponentially greater damage on enemy forces and ecologies.

During World War I military strategies of both the Entente and Central Powers focused sharply on trench warfare, devastating large segments of the European landscape particularly in northern France. While trench warfare had been a significant military strategy since the Napoleonic Wars, the increased power of munitions caused greater damage to the ecology, both directly as a result of deployment on the battlefield and indirectly as factory mass-production of munitions consumed larger amounts of raw materials.

The largest global ecological impact of World War I was on timber. Other than the forests of Russia, which resided in predominantly inaccessible regions, European forests endured heavy exploitation as nations rushed to fuel the war machine. With the local wood supply dwindling, timber was imported into Europe from forests in North America and South Asia, causing ecological decline in those regions. In the postwar years, governments took more direct control over their forests, and while new trees were planted to replace their felled counterparts, single-species tree plantings took the place of naturally diverse forests.

Chemical warfare was first employed in World War I when German forces unleashed chlorine gas near Ypres, France, on April 22, 1915. World War I has been commonly referred

to as the chemists' war. Although Germany may have introduced the world to chemical warfare, the rest of the world quickly followed. By the end of the war, clouds of mustard gas, chloropicrin, hydrogen cyanide, diphenylchloroarsine, and arsenic drifted over Europe. While scientists helped create chemical weapons, they also engineered civilian usages for these chemicals, such as insecticides, after noting how battlefield regions were emptied of insects.

As the world became increasingly industrialized moving toward World War II, the pressure on the global ecology was heightened. An increased reliance on aerial bombing raids in World War II was the largest in-war impact on the European ecology, but the ever-greater need for timber devoured forests in Norway, Poland, British Columbia, Oregon, and Washington state, which in turn led to postwar civilian expansion into previously unsettled or lightly populated regions.

Chemicals played their role, too. Created in 1873, Dichlorodiphenyltrichloroethane (DDT) was not used as a pesticide until shortly before World War II. In the war, DDT helped ensure greater control over battlefield ecology, helping to kill malaria-transporting mosquitoes and typhus-transmitting lice. These short-term benefits led to long-term ecological harm, however, as DDT has been linked to cancer in humans and the near-extinction of several species, including the bald eagle.

The signature event of World War II was the dropping of the atomic bomb, first on Hiroshima on August 6, 1945, and then on Nagasaki three days later. While the bomb devastated the two cities and their inhabitants, the ecological impact has proven to be dramatically less harmful. Within days of the detonations, residual radiation had dissipated to nonthreatening levels, and flora and fauna survived, if not thrived, in the immediate aftermath. While the animals caught in the blast certainly died, mosquitoes, flies, fish (in deep water), rats, and earthworms in the vicinity all managed to survive. Remarkably, these organisms suffered little long-term health risks associated with the blast. Trees also sprouted new twigs within months. While human victims suffered the consequence of exposure to radiation and fallout for decades to come,

French soldiers launch a gas and flame attack on German trenches in Belgium during World War I. (National Archives)

➤ THE PLANNED POSTWAR DESTRUCTION OF GERMAN FORESTS

At the Potsdam Conference of August 1945, Allied Forces divided a defeated Germany into four military occupation zones. As part of the postwar policy, Allied plans called for both the exploitation and destruction of German resources. This plan was not implemented in a united manner due to Cold War antagonisms. One United States government plan proposed:

"In accordance with this policy, a forestry program has been initiated in the U.S. Zone to furnish timber to satisfy current military and essential civilian needs, to provide exports, and to build up stockpile for future requirements. Approximately 23,500,000 fest meters of timber (about 200 percent of annual growth), will be cut in the year ending 30 September, 1946. . . . As a basis for developing a future program looking toward total control and ultimate destruction of the war potential of German forests, a complete inventory of forest resources in U.S. Zone is being made."

Interwar Global Depopulation

Depopulation patterns in the period following World War I resulted from large-scale famine, war, and disease in many of the world's regions, particularly in Europe and Asia. The onset of the

destruction brought about by the Great War led to the upheavals and dislocations that transcended the war, such as the Armenian Genocide, the Russian Civil War, the Greek and Turkish population transfers, and the British blockade of Germany, all of which resulted in significant casualties in Europe. In Asia, large-scale famine and endemic warfare took their toll, particularly in interwar China. Global depopulation during the interwar period (1919–1939) was a staggering phenomenon, with warfare, economic chaos, and a major postwar outbreak of the Spanish flu as the major contributing factors.

Interwar European depopulation was directly related to the aftermath of World War I. Political efforts to rid Turkey of its Armenian population led to the estimated deaths of 1.5 million Armenians through genocide at the hands of the Turkish military. The British naval blockade of Germany, instituted to force the German leadership to sign the Treaty of Versailles, led to the deaths of approximately 750,000 Germans. In the Greek-Turkish War (1919–1922) and during the population transfer that followed, mutual ethnic hatred and chaos led to the deaths of thousands of civilians and combatants on both sides. During the population transfer, approximately 1.5 million Greeks and an estimated 500,000 Turks shifted between Greece and Turkey. The Russian Civil War, which ravaged much of European Russia from 1918 to 1922, led to the deaths of 20 million combatants and civilians. Along with the hardships imposed by the global economic depression in the 1930s during which the birthrate dropped, European population patterns somewhat stabilized in spite of all these events before the onset of World War II.

Events in interwar China, stemming from the conflicts between the Guomindang or Nationalist Party of China (KMT) and the Chinese Communist Party (CCP) and their mutual adversaries, the Japanese, along with the economic and political instability unleashed by endemic warfare, led to millions of deaths across much of the region in the 1920s and 1930s. Endemic warfare between the KMT and its persecution of the CCP in the 1920s led to the deaths of tens of thousands of Chinese combatants and civilians. Japanese attacks on Chinese cities and the invasions of Manchuria, Jehol, and Nanking led to the estimated

► FRENCH FIN-DE-SIÈCLE POPULATION FEARS

Prior to World War I, prenatal policies in France were geared toward addressing the issue of a declining French population, particularly that of males. While Germany's population steadily grew in the period following the Franco-Prussian War (1870–1871), the French population's birthrate had experienced a steady decline. Both French conservatives and republicans blamed French women and feminism for this phenomenon. French government policies addressed this by arguing that French women had the duty to provide the Republic with babies and offered some incentives. Economic incentives and suggestions for prenatal health care, among other policies, were discussed by the French government as a way to encourage pregnancy. Concerns over the virility of the French Republic in the early twentieth century vis-à-vis growing German world power contributed to this sense of malaise. Until the outbreak of World War I, French depopulation was a top political concern.

—Abraham O. Mendoza

deaths of millions of Chinese combatants and civilians. Due to conflicting reports by historians, there is no way to arrive at an accurate number of total casualties incurred during the whole interwar period in China, but estimates are that approximately 20 million Chinese died from the Sino-Japanese War (1937–1945), which constitute a significant portion of the approximately 70 million deaths (both combatants and civilians) during the whole of World War II.

Although other world locations were not spared the economic dislocations caused by the Great Depression, they were spared the warfare that characterized the interwar period in Asia and Europe. Nevertheless, the Spanish flu outbreaks of 1918 did lead to the estimated deaths of anywhere between 20 million and 100 million people the world over. Given the lack of reliable estimates of the global population during the interwar period, the approximate number of deaths and lowered birthrates suggest that the global population either declined or merely stabilized significantly in contrast with the period before 1914, which was characterized by steady growth.

Total War and Population— Civilian Deaths in World War II

The level of destruction of World War II affected civilian populations on a scale unknown up to that time. Through attacks on civilians, combat deaths, the toll of concentration and death camps, ubiquitous starvation, and disease, World War II resulted in the deaths of an estimated 50 million to 70 million people. The home front was as significant a target as the battlefield given the view that it was strategically important to strike at the economic capacity of the

> BANALITY OF EVIL AND TOTAL WAR

In her book *Eichmann in Jerusalem* (1963), philosopher Hannah Arendt examines the case of SS-Obersturmbannführer, a top Nazi official responsible for the coordination of Jewish population transfers from the Eastern occupied territories to concentration and death camps. Arendt argues that Eichmann, as a bureaucrat responsible for the deaths of millions by signing orders, gradually became detached from the responsibility of the Final Solution. Eichmann believed that he personally was not involved in murder, as he was “following orders” from above while others were carrying out the “actual” work. The concept of the “bureaucrat” as a dispassionate murderer illustrates the level of detachment that characterized modern total war, as soldiers, civilians, and government officials made decisions on a day-to-day basis that led to the deaths of millions.

—Abraham O. Mendoza

other side to wage war. With the exception of the United States, most of the major belligerents in World War II were exposed to attacks on their civilian populations. In the initial years of the war, Germany and Japan devastated their respective enemy populations through massive military invasions, the destruction of major urban centers, and the persecution of racial or political enemies. In kind, the British and U.S. forces, through major strategic bombing attacks, leveled major urban centers, aiming to destroy not only industrial centers but also their adjacent populations. The Soviets extracted extreme retribution as they beat the German forces back into the Reich, enacting vengeance on German civilian populations.

While prior wars, such as the Napoleonic Wars, the American Civil War, and World War I, were arguably examples of total war, World War II is by far the most definitive example of mass civilian involvement, as technological advances helped blur the distinction between the battlefield and the home front and as civilians became viable targets by their respective antagonists. Prior conflicts, which had high levels of state involvement and economic mobilization of civilians, did not place the majority

MANHATTAN PROJECT, ATOMIC PRODUCTION, AND ENDANGERED CIVILIANS

With the pressures of World War II and its attendant crisis mentality, safety standards for domestic labor in the war industries became of lessened importance. In this sense “total war” extended not only to the enemy but to domestic populations of civilians. One of many examples involves the use of approximately 125,000 civilians at the scattered sites of the Manhattan Project, the U.S. military’s code name for its secret effort, begun in 1942, to develop the atomic bomb. In addition to the Los Alamos, New Mexico, site where physicists and engineers worked on the theoretical aspects of creating and assembling the bomb, other large facilities included an Oak Ridge, Tennessee, site dedicated to processing uranium and a Hanford, Washington, site dedicated to plutonium processing.

None of the Manhattan Project’s 125,000 workers knew the precise nature of the project or the health risks. While the industrial standards for handling hazardous materials were enforced, these measures were far from sufficient for work with

radioactive materials. According to historian Peter Hales, in addition to unintended worker exposure to radioactive materials, at least 50 subjects (including patients admitted to hospitals for other symptoms) were intentionally and secretly exposed to plutonium to gather data on its effects.

The plutonium processing in Hanford, Washington, which began in 1943 and continued throughout the Cold War led to extensive radioactive pollution of the region. In 1989 the U.S. Environmental Protection Agency concluded that 230 square miles of ground water in the Hanford Reservation area were unfit for any human use.

—Fred Nadis

Bibliography

of the civilian population in harm’s way. New weapons, including tactical bombers—such as British Lancasters and U.S. B-17 Flying Fortresses—equipped with blockbuster and incendiary bombs, brought death and destruction to the enemy directly. British, Soviet, German, and Japanese populations felt the brunt of bombing attacks on their urban populations, particularly those adjacent to industrial areas pivotal for war production. So-called morale bombing, justified by the premise that civilian populations would turn against their respective government authorities, proved to be ineffective, although it was continued by all sides. The dropping of the atomic bomb on Hiroshima and Nagasaki in August 1945 remains the culminating example of the bombing of civilians as a main target in total war.

The displacement of large numbers of people, through military liquidations, forced migrations to ghettos, concentration camps, death camps, and slavery, also contributed to the megadeaths of World War II. In Nazi-occupied Europe, as millions of Jews, homosexuals, communists,

and other “misfits” were persecuted and subject to incarceration, upwards of approximately 10 million died (with an estimated 6 million of them being Jews) under German and collaborationist authorities. As the Allied armies closed in from both sides, Axis civilians were exposed to acts of retribution at the hands of their enemies now on the offensive. Particularly on the eastern front, the Red Army subjected German populations to rape, murder, and starvation, justified as vengeance for similar acts committed by the German Wehrmacht and Waffen-SS in the formerly Nazi-occupied Soviet territories. Upwards of 11 million Germans were expelled westward into the Reich, with approximately 2 million dead through shootings, starvation, and other acts of retribution from 1945 to 1948. Former collaborators or people suspected of collaboration were also subject to murder by locals under the jurisdiction of Allied occupational authorities who permitted such actions by turning the other way, particularly in France (with such casualties estimated in the tens of thousands).

Restoring the Landscape— Clearing Up Battlefield Damage

Along the western front, the battles of World War I destroyed millions of acres of formerly productive agricultural land. Previous military engagements, characterized by bayonet charges and short-range artillery fire, resulted in the deaths of thousands in battle but had relatively little impact on the actual terrain. What was left following World War I was a virtual moonscape created by artillery barrages, pounding hundreds of thousands of shells for thousands of square miles, mostly in the French northeast and southeast and along the Belgian border with Germany. The large battlefields of the Somme, Verdun, and Ypres were vast landscapes of destruction fraught with ubiquitous shell holes, barbed wire, destroyed pillboxes, and shattered trenches. Adjacent surroundings, such as forests, pasturelands, and villages, also were affected. As German troops retreated in the last year of the war, they poisoned wells, burned villages, and destroyed infrastructure, further contributing to the damage. The reclamation and reconstruction of these moonscapes took a considerable amount of time and conscripted labor to accomplish.

Battlefield damage in the Somme, Verdun, and Ypres, in addition to other smaller battle sites on the western front put millions of valuable acreage out of production during the war. Efforts by the French government and the British Expeditionary Forces to assist local farmers struggling to continue their livelihood in the midst of the war were unsuccessful. Following the war, German prisoners of war, Chinese coo-

➤ SUBMARINE WARFARE AND OCEAN POLLUTION

While ship sinkings characterized naval warfare before World War I, the volume of large convoys running between North America and the British Isles and the incidences of submarine attacks during World War I increased such incidents dramatically. German naval authorities recognized that Britain relied on its foodstuffs from overseas and viewed its supply as a viable war target to provoke starvation and thereby surrender. As a result, in addition to loss of human lives, untold amounts of destroyed British and American ships littered the routes between Britain and the United States, polluting the ocean with debris, petroleum, and other wastes. This practice continued in World War II on a greater scale, generating far more ocean pollution. To this day, sunken vessels continue to rot away and spill fuel, illustrating the continuing impact of war on the oceans.

—Abraham O. Mendoza

lies, and other bonded labor were conscripted to aid in the restoration of the land, working with French and Belgian military authorities in the removal of shell casings, barbed wire, duds, and destroyed structures along the miles of trenches. This was dangerous work given the large number of unexploded shells that could be easily triggered during reclamation efforts. The scale of these efforts was enormous due to the vast terrain, which had been affected by hundreds of miles of trenches with their requisite structures and adjacent battle damage. The cost of this entire undertaking was added to the reparations imposed on Germany in the Treaty of Versailles of 1919. Ninety years later, unexploded shells are still found by French farmers, illustrating the continuing danger from World War I's implementations of war.

National Socialism and Environmentalism

The implementation of environmental regulations under the National Socialist regime has supposedly sustained a myth about the green policies enacted in Nazi Germany and how the Nazis might have perhaps been the forbearers of the modern Green movement. There is some credibility to the underpinnings of this scenario: National Socialist ideology did invoke the importance of sustaining the German landscape, but it did so in tandem with the idea that it was vital for the purpose of upholding the racial purity of the Aryan race. The paradigm that blood and soil were inextricably tied played an important role in the adoption of environmental policies within the Third Reich from 1933 well into World War II. However, there is also evidence to suggest that while some Nazis were eager to preserve the environment and use scientific

management for soil and forestry, as the regime mobilized for a total war economy environmental policies became mere rhetoric and were gradually ignored.

While environmental organizations did exist in both Wilhemine and Weimar Germany, they were mostly at the grassroots level and active within individual German states (*Länder*). Most of these were nature protection groups (*Naturschutz*) or youth hiking clubs (*Wandervogel*) that advocated the protection of the natural environment from industrialization and urbanization. The group membership believed that the German landscape was vital for the preservation of German culture and history, which was threatened by increased modernization. Most of the rhetoric espoused by these groups mirrored the type of language used by advocates of the *völkisch* (“folk”) movements, who mixed ethnic nationalism with nostalgia for the preindustrial German past. Many of these advocates argued that the purity of the German people was tied to the fate of the German landscape and that the threat by “foreign” species and the destruction of the natural environment by the process of modernization (which was associated with Americanization or consumer culture) was akin to the threat to the German race by the influx of foreigners. The analogy between blood and soil emerged out of this relationship between these various groups.

When the National Socialist regime came into power in 1933, some top Nazis were responsible for enacting environmental legislation as they co-opted the agenda of the various German environmental organizations. The Reich Nature Protection Law of 1935, put in place under the National Socialist regime, enacted national environmental legislation throughout Germany and thereby took initiative that was formerly left to the various states. Scientific management of forests, as advocated by Nazi leader Hermann Göring, was implemented for the conservation of Germany’s forests (*Dauerwald*). As a hunter, Göring was an advocate for the preservation of the natural environment and game. First minister of agriculture Richard Walther Darré, seen as a proto-Green by some historians, utilized the term *Blut und Boden* (“blood and soil”) to identify and advocate sustainable agricultural prac-

➤ MORGENTHAU PLAN (1944)

As the Grand Alliance closed in on Nazi Germany, the Allies were planning for the eventual defeat of Germany and its postwar configuration. At the Second Quebec Conference in 1944, British and American officials agreed on the Morgenthau Plan, proposed initially by U.S. secretary of the treasury Henry Morgenthau Jr., to dismember and de-industrialize Germany, thereby making it “a country primarily agricultural and pastoral in its character.” This punitive proposal was based on the premise that Germany’s ability to wage war could only be destroyed by the removal of industry and the division of Germany into two states, with many regions either under international control or annexed by neighboring countries. While top U.S. and British officials initially supported this policy, they were convinced by military commanders that it would ensure resistance in the German population, not to mention remove the de facto economic industrial center of Europe in a time of expected economic hardship. A more moderate policy was enacted in the postwar period, and the Germanies (West and East) remained formidable industrial powers rather than the pastoral state envisioned by Morgenthau.

—Abraham O. Mendoza

tices throughout the Reich. Other policies under the Nazi regime, such as air pollution control, autobahn landscaping, and the extensions of environmental policies into the conquered territories, were upheld by various Nazi officials.

Some historians argue that Adolf Hitler's co-optation of all national organizations under the National Socialist umbrella convinced him that environmental policies were a good way to gain support for all the regime's policies. Nevertheless, as Nazi Germany mobilized for total war, many of these conservationist policies were ignored, as the use of natural resources was seen

as pivotal in the production of munitions and matériel.

Society and Culture

From 1900 to 1945 throughout much of the world, the social landscape was altered by the onset of modernization. Mass production, improvements in transportation and communication, and other new technologies altered daily life and attitudes. Such technological offshoots of the accelerating Second Industrial Revolution manifested mostly in Europe, North America, and Japan but followed in other areas with comparable levels of economic development. An accompanying growth of consumer culture, mass media, and advertising also characterized these developments, again primarily in the developed West. Many embraced the promises of modernity, while others, seeing traditional ways threatened, rejected the altered landscape. Modernization and its critique along with nationalism and its many variants (including anticolonialism) were important culture shapers in this period. World events, including World War I, the Great Depression, and World War II, channeled these forces as they swept through and transformed much of the world.

Once-peripheral political ideologies such as communism, socialism, and fascism, with their accompanying political, economic, and social models of organization, gained traction during this period. While many of these ideological movements had existed before this period, the collapse of social and economic order in the interwar period allowed them to capture significant levels of popularity within the mass of society. Nationalism, which invariably accompanied the development of the modern nation-state, intensified in response to the disorder and anxieties of the period from 1900 to 1945, most notably communism and fascism.

Rigid class distinctions between the middle class and the working classes still characterized much of the social structure in Europe and other industrialized areas in this period, albeit with a continued decline in the influence of the hereditary aristocracy. Despite the rise of new commercial, military, and political elites, the middle class continued to gain influence in government and society. During the world wars, greater proportions of the population of several European countries gained political agency under republican forms of government.

Workers also sought increased autonomy but with limited success. The triumph of the communist-inspired Bolshevik Revolution in Russia as well as the generally exploitative conditions imposed on industrial and agricultural laborers led to a powerful worldwide labor movement during this period in which bitter animosity, general strikes, and violent confrontations were common. Labor gains tended to be strengthened during the economic crisis of the 1930s as governments sought to quell social unrest and lessened when nationalistic concerns tempered

labor demands during the book-ended war years. The emerging global nature of industrial production encouraged the strengthening of international associations of labor unions.

During this period there were significant advances in the position of women in many areas. Suffrage movements led to the franchise for

Advertising in Europe and North America

heralded images of the “New Woman,” often thin, athletic, glamorous, free-spirited, and shown in the driver’s seat of an automobile.

women in Europe, the United States, and Canada and in much of Latin America and Asia as well. Advertising in Europe and North America heralded images of the “New Woman,” often thin, athletic, glamorous, free-spirited, and shown in the driver’s seat of an automobile. Contrary to these images, in most parts of the world—consumer havens included—women were

still socially and legally subordinate to their fathers and husbands. Nonetheless, new educational opportunities for women and new clerical professions allowed for women’s increased participation in the job market. The need to ensure an adequate domestic workforce during the world wars also brought many women into industry, as most of the men had gone off to fight. Government advertising encouraged women to join the workforce as a patriotic duty, wedding nationalistic fervor to emancipation and generating such mythic figures as “Rosie the Riveter” on posters in the United States during World War II. Within this context, women gained a degree of independence within society.

Racial hierarchies were also reinspected, challenged, and reinvented. The Black Freedom movement in the United States included such efflorescences as the New Negro Movement of the 1920s and the Harlem Renaissance of the 1920s and 1930s. Under the leadership of W. E. B. Du Bois, the first Pan-African Congress was held in Paris in 1919. Delegates to the congress underlined the parallels between the oppression built into colonial regimes and other societies. Negritude, the literary movement that began in the 1930s among North African expatriates in France, took inspiration from the African American literature of pride and protest and its accompanying exploration of identity. At the same time, throughout Asia literary and artistic movements explored how the imposition of Western cultural standards and colonial racial hierarchies affected traditional local identities. Efforts to promote a Pan-Asian style under Japanese leadership foundered as Japanese ultranationalism and Japan’s military campaigns to carve out the “Greater East Asia Co-Prosperity Sphere” revealed clear imperial ambitions that did not mesh with its anticolonial rhetoric.

The degree to which colonialism shaped the populations of much of southern Asia, Southeast Asia, and Africa is a matter of scholarly debate. In some areas, such as Hawai’i, colonial powers ruled through the local power structures. In other areas, particularly in Africa, they established direct rule, taking responsibility for functions such as collecting taxes and maintaining order. While the traditional organization of many of these societies survived colonialism, the military might of the colonial power was always a factor. Native elites were generally heavily influenced by the colonial homeland culture and were often educated in Euro-

pean universities. These well-educated colonial subjects typically served colonial authorities but eventually became the major source of dissent, and many were to become leaders of movements demanding greater autonomy and outright independence. Their numbers included Mahatma Ghandi, Jawaharlal Nehru, Jomo Kenyatta, Sun Yixian (Sun Yatsen), and Mao Zedong. These well-traveled educated men often brought home nationalistic fervor as well as new political and social ideologies (such as socialism and communism), contributing to a growing sense of national identity and a desire to end foreign imperial dominance.

States outside European control but within European economic hegemony, particularly those in Latin America, the British Dominions, and China, while able to retain much of their traditional social structure, were nonetheless exposed to change. The Latin American republics, nominally independent but subject to European and U.S. economic domination, experienced the rapid modernization of their major cities, in contrast with the provincialism of their traditional rural hinterlands. The clash between the modern urban centers and the traditional rural countryside shaped much of the political dynamics of Mexico, Argentina, and Brazil. The liberal cities, heavily influenced by European culture and ideas, found themselves confronted by the lingering political influence of landowners who wished to maintain their control over the economy and social order. The British Dominions, most notably Canada, Australia, and New Zealand, also were shaped by this conflict between their modernizing metropolitan centers and their vast agricultural interior lands.

To a significant extent, countries such as the United States, Japan, France, and China also faced these “culture wars,” which pitted the “traditional” against the “modern.” The reaction often took the form of a grassroots nativism antagonistic to immigrants or outsiders. Notable in the United States was the rebirth in the 1920s of the racist and nativist Ku Klux Klan, whose members defended what they viewed as a “pure” Anglo-Saxon Protestant identity and purported to uphold traditional values against the perceived forces of modernity and social change. Elites also took part in such nativist and racist backlashes. For example, the eugenics movement, embraced by elites in Europe and the United States, proposed a genetic theory of the superiority of certain races and directly led to legislation limiting immigration and to some sterilization campaigns.

Such ideas took a particularly ugly turn in Germany after World War I. Disillusioned Germans, believing themselves to have been betrayed, embraced extremist political positions, leading to the rise of the National Socialist Workers Party of Germany (Nazi Party). Caught up in the romantic mythology of a racially pure tribal past, Nazi Party members reordered German society along ideological lines. Their goal was to eliminate the racially defective or impure—such as Jews, Gypsies, homosexuals, and deformed persons—from social and civic life. The Nazis expropriated the properties of these “impure” persons and confined them to work camps, which ultimately became death camps. The Nazis created institutions that attempted to militarize the entire society and channel it to their ideological goal of forging a racially pure Third Reich.

To this end, German media and propaganda promoted the invented category of the Aryan as a racial ideal. For example, in the “mountain films” directed by Arnold Fanck, actress Leni Riefenstahl and other healthy young comrades climbed boldly to the purifying summits of mountains. In the documentary *Olympiad*, Riefenstahl, as a director, glorified the 1936 Olympics in Berlin and highlighted German athletes

and their muscular bodies. According to German National Socialism, much of modern art, thought, literature, and science was condemned as degenerate, damned by its association with Jewishness. The Nazi ideology of ethnic “purity” underpinned Germany’s military expansion and led to the deaths of millions.

This dramatic restructuring of society along totalitarian lines also occurred in the Soviet Union. As in Nazi Germany and ultra-Nationalist Japan, new institutions were forged and new traditions invented that ensured centralized control and local obedience. An idealistic arts community in Russia had first welcomed the Bolshevik Revolution and seized upon modernist experimentation to celebrate the new era. Figures such as the poets Vladimir Mayakovsky and Anna Akhmatova, filmmakers Sergei Eisenstein and Dziga Vertov, Constructivist artists Vladimir Tatlin and Kasimir Malevich, and fiction writer Isaac Babel all celebrated the dynamism of the revolution in their art. Many later despaired, were killed in purges, committed suicide, or grudgingly adjusted as Soviet arts ossified into a wing of party propaganda.

The United States in this period also, but to a far lesser extent, went through a period of social “reinvention.” Faced with economic collapse and social unrest, the United States was able to establish a welfare state along liberal lines and increase the role of the federal government. New Deal legislation and institutions established greater government intervention in the economy to offset abuses and shortcomings in the free market, left unchecked by a lack of regulation. While less ideological than the Soviet or Nazi models of political domination of social institutions, the New Deal was decisive in changing American expectations of the responsibilities of government. At the same time the New Deal had its own nationalistic trimmings such as the National Recovery Act (NRA) flags that draped streets and the “Blue Eagle” poster that appeared in the windows of cooperating stores. New Deal programs also helped fund the arts and literature, shaping public works, public sculpture, and architectural adornment. The Great Depression also engendered a new aesthetic that heralded the common man and American folkways in art and literature. Fiction and nonfiction studies of the abominable living conditions of sharecroppers, hoboes, agricultural workers on the new “factory farms,” and the struggles of factory workers became common.

Worldwide, architecture, design, literature, and the arts absorbed the modernist impulse. Ultimately, modernism offered a new sense of style for cultural products packaged for mass audiences. Modernism

had two main streams—both inspired by the revolution in scientific knowledge of the late nineteenth and early twentieth centuries—and the accompanying overturning of inherited “truths.” The first stream of modernism, which might be termed “rationalist,” sought to apply a machine age aesthetic to the built environment. Architects, designers, and planners rejected the revivalist approach of recycling classical forms and instead searched out new forms made available via new mechanical means and materials; the underpinning ideology was to organize and ennoble society via technocratic means. The second stream of modernism might be described as “antirationalist” or “therapeutic.” Repulsed by World War I’s carnage and the stultification of industrial labor, artists seized upon the Freudian theory of the subconscious—a fascination with the dream, spontaneity, and the so-called “primitive”—to reject all tradition, particularly Western tradition, and to move to more abstract or confrontational art forms. This impulse could be seen, for example, in the development of atonal music, which rejected the authority of former theories of harmony and composition.

To the extent that it fit the needs of the emerging consumer society—give or take a few opening night riots—modernism was hardly a

disruptive force. During the 1930s, manufacturers sought ways to redesign products and stimulate consumption; as one direct result, industrial design, an offshoot of modernism, came of age. Streamlining in architecture and design—the effort to render buildings, lobbies, automobiles, trains, roadside diners, pencil sharpeners, and toasters with curvilinear lines and smooth surfaces that suggested aerodynamic designs—became prevalent in the 1930s, seized upon by both totalitarian and democratic states. The modernist rejection of constrictive social codes regulating sexuality and leisure also fit the new commercial age. More libertine norms became common; former “vices” such as smoking offered big business opportunities as advertisers sought to sell to new market segments, such as cigarettes designed specifically for the sophisticated “new woman.” Through the 1930s and 1940s jazz lost its low-culture association, and the big band jazz sound became a soundtrack to accompany the rise of the middle class. Just as modernists had explored the subconscious and dreams, the mass arts as expressed through film, radio, phonograph records, and industrial design reforged the daily lives and dream scripts of millions worldwide.

and Fred Nadis

■ Introduction: Class and Gender

In various cultures gender and class relate in different ways, and during the Industrial Revolution they became linked in a very specific manner. Although “working class” women labored in the factories or entered into “service” as maids, cooks, or nannies, having a wife at home was an important status marker for the middle class. The separation between public and private spheres, institutionalized by the new economic and social realities, created an even greater division between the middle class male and female spheres. Going to work in the morning, trading vigorously in the stock market, and competing in the men’s world of the imperial free market, men were expected to be active, as-

sertive, dominant, and domineering. On the other hand, women, staying at home cooking, taking care of children, cleaning the house, doing the laundry, and preparing the table for their husbands’ guests, were expected to be passive, shy, submissive, and docile. These socially constructed gender differences were perceived as the natural order. Men like Sigmund Freud, who made a habit out of shocking the prudish Victorian society, believed that this was a natural or biological order of things. A few feminists today are still outraged at his idea of phallus envy as the key to a woman’s personality, while others recognize it as “power envy.” In that sense, Freud was a typical early-twentieth-century bourgeois

▶ PERFORMING FEMININITY

“A woman of [30 years old] often frightens us by her psychical rigidity and unchangeability. . . . [I]t is as though . . . the difficult development to femininity had exhausted the possibilities of the person concerned. . . . If you want to know more about femininity, enquire from your own experiences of life, or turn to the poets, or wait until science can give you deeper and more coherent information.”

—Sigmund Freud, founder of psychoanalysis

“The reader may now ask how I define womanliness or where I draw the line between genuine womanliness and the ‘masquerade’. My suggestion is not, however, that there is any such difference; whether radical or superficial, they are the same thing.”

—Joan Riviere, Freud’s translator and patient, herself also a psychoanalyst

—Judith Kegan Gardiner

except for the fact that he expressed typical bourgeois ideas in a typically provocative Freudian manner.

On the other hand, the history of gender relations and gender identity in the first half of the twentieth century developed in sharp contrast to the perceived prudery of the Victorian period. Periods of sexual prudery were nothing new in history, but in the Victorian period sexual mores were not just religious or cultural customs. Their love affair with new ideas about science led them to link their perceptions of sexual propriety with scientific medicine of the time. For example, it was widely believed that masturbation caused tuberculosis. For the Victorians, breaking the code of proper gender behavior became not just a social indiscretion but also a socially subversive behavior. Many people tested the boundaries of Victorian sexual moral-

ity, which promoted, at least in public, the view that sex outside marriage, including adultery, masturbation, premarital sex, and prostitution, were unhealthy perversions. This hostility to societal norms was especially popular among the left-leaning circles, which saw Victorian sexual mores as part of the bigger picture: a repressive and exploitative economic-social system. Then suddenly, at the beginning of the twentieth century, physicians such as Freud started arguing that sexual abstinence and repression cause medical and psychological problems.

The stage was thus set for several waves of sexual revolution of the twentieth century and the enduring conflict between the traditional and the modern view of sex and gender. The most important gender-driven conflict in this era occurred during the Roaring Twenties. Right after World War I, gender became a cultural battlefield from Puritan America to Soviet central Asia. Many women pursued liberation from traditional restraints; many others were pushed by popular or even political culture to embrace modernity. The Soviet Union of the 1920s tried to “emancipate” women, with some success. Some were “emancipated” by force, such as was the case in central Asia. The gender revolution in Russia was put in check by Josef Stalin. While Hollywood did not try to remove the veil from traditional women by force, it put forward a prototype of the femme fatale or “modern woman.” That prototype was based on the flapper, the typical liberated woman of the Jazz Age who ignored social conventions. But the type was also a male fantasy, and through the new medium it exerted social pressure on millions of young women, who tried to live up to an impossible standard.

Women first achieved political liberation; gender equality was slower to follow. The suffragette movement, active since the middle of the nineteenth century in all industrial countries, finally triumphed after World War I. As originally promised by the Enlightenment, the wave of giving women their inalienable voting rights traveled the globe. By the time of World War II, a sexy working woman in overalls—Rosie the Riveter—became not just an American icon but a global icon.

Political equality, however, does not imply gender equality. The crucial contributions to-

ward gender equality were made gradually. At the end of the first half of the twentieth century, the book *The Second Sex*, published in 1949 by Simone de Beauvoir, attempted to explain what it meant to be a woman. The partner of French existential philosopher Jean-Paul Sartre, de Beauvoir noted “one is not born, but rather becomes a woman,” emphasizing the difference between biological sex and socially constructed gender. De Beauvoir’s book became the basis for subsequent sexual and gender revolutions that occurred in the later half of the twentieth century. The book helped create feminism, and even though it affected feminists largely in the later part of the twentieth century, it summarized the experiences of a woman living through the first half of the century. *The Second Sex* became a worldwide best-seller primarily because it said something essential about how gender and class were constructed during the era.

—Alexander Mirkovic

The Middle Class

Defining the middle class in world history is problematic not only because of the varying levels of wealth present within the class but also because the middle class rose in different countries at different times. In western Europe and the United States, the middle class rose as a result of the Industrial Revolution, which took place during the late eighteenth and early nineteenth centuries. Until this time, artisans and skilled craftsmen had labored in the home or workshop with their families to produce goods. This cottage industry had required no formal payroll, overseers, time clocks, or machinery. Following industrialization, goods were manufactured rapidly in large factories by unskilled workers. Artisans lost out completely and were often forced to join the workmen in the factories. In addition, foremen and managers were also needed to oversee production and to monitor breaks and tardiness. These managers and foremen became some of the earliest members of the middle class. The modern working class was also forged by this transformation.

Leisure culture also developed as the middle class emerged, leading to a wider variety of busi-

THE MIDDLE CLASS AND CONSUMER CULTURE

The formation of a middle class greatly influenced the growth of consumer culture in the late nineteenth and early twentieth centuries. Middle-class respectability hinged on society’s perceptions of a family’s behavior, clothing, and homes. The typical middle-class home was expected to have books, tasteful artwork, and elegant furniture. To make this possible, a portion of the family budget was spent on comfortable furnishings, clothing, and books. Department stores allowed middle-class women to do much of their shopping in one place, which was both convenient and tempting. Many women were criticized during this time period for overspending and running up charge accounts. This lack of frugality drew criticism from the upper classes and angry husbands. Entertainment was also important to middle-class families. Many such families traveled frequently, and a number of them even took yearly vacations, which led to a steady growth of the tourist industry. Middle-class people of all ages made up a large percentage of moviegoers in the early twentieth century as well. Amusement parks also had a large number of middle-class customers. Overall, the middle class spawned whole new arenas of consumerism because they had the expendable cash to do so, unlike their working-class contemporaries.

—Christi McCallum

nesses such as department stores, amusement parks, and dance halls. Consequently, this too increased the ranks of the middle class by providing even more jobs. In East European countries, the development of the middle class as a separate culture was somewhat delayed by industrialism’s late start, and in many of these areas it was the end of the nineteenth century or the beginning of the twentieth century before a separate middle-class culture evolved.

Industrialism and imperialism had expanded the West European and American middle classes and made them quite wealthy during the course of the nineteenth century. At the same time, the middle class had dominated politics and set social norms during what some historians have called the century of the middle class, or the period between the beginning of the French Revolution (1789) and the beginning of World War I

(1914). The middle class from its inception had embraced the political ideas of liberalism and nationalism. However, the late nineteenth and early twentieth centuries were a time of class struggle as well. The middle class's dominance would come to be challenged by working-class labor movements in western Europe in the years preceding World War I.

Generally, the middle class at the turn of the century had fewer children, and the family unit had become very close. The ideal middle-class family at this time included the mother as nurturer, father as breadwinner, and well-mannered boys and girls who went to school on a regular basis. Gender roles were rooted in Victorian ideologies concerning the so-called cult of domesticity, the belief that women's place was in the home. Women were considered important as wives and mothers and held some informal authority as such. However, the repression of such structures would also spawn women's movements, most notably suffrage and philanthropic movements that would be most popular with the middle class. Homes of the middle class became increasingly located on the outskirts of cities in the suburbs or even completely removed from the city in the countryside. At the same time, morals and religion were generally important to the middle classes, although this shifted increasingly following the late nineteenth century as middle-class intellectual and cultural values were challenged by new social ideologies, such as Sigmund Freud's psychological studies, and scientific theories, such as Darwin's theory of evolution. Due to greater access to books and education in the universities, the middle class would be influenced more by these intellectuals than would the working-class individuals, who were generally much more caught up in the struggle for survival and, as a result, were often more religious or superstitious in nature.

Overall, World War I served to unify nations, and many of the social conflicts were displaced onto the battlefield. Many upper- and middle-class soldiers had not experienced manual labor alongside poorer members of society before fighting beside them in World War I trench warfare. The war, far from being the quick victory imagined by the middle and upper classes, was lengthy, bloody, and destructive. Moreover, World War I

unbalanced the economies of many European countries, which resulted in changes to the boundaries between classes and genders.

In most European countries, World War I resulted in a narrowing economic gap between the middle and lower classes. At the same time, the war led to increased animosity between the middle class and the working class, as the middle class struggled to maintain a separate class identity. In addition, many women had entered the workforce for the first time during World War I and this combined with the achievement of women's suffrage that followed the war was a threat to the idealistic middle-class family structure. However, many middle-class families of the 1920s and 1930s could not afford to keep women home any longer because of gross inflation and lack of employment.

Economic crises across Europe in the 1920s were exacerbated by the collapse of the U.S. stock market in 1929. In the United States, the Great Depression left many middle-class families as poor as the working classes. In Britain and France, the lines between the middle class and lower classes generally disappeared, leaving a simpler class system, with the rich who did not lose their assets at the top and the rest of the countryside at the bottom. While many other European countries were plunged into economic despair, Britain recovered by implementing the national government (a blend of three domestic governments, including the labor government) in 1931. This effectively ended class struggle in Britain by uniting conservatives, liberals, and labor parties. The middle class in England had not lost everything as the German middle class had during World War I, and this kept fascism and other such ideological threats at a minimum in England. In other countries the middle classes sometimes turned to fascism, although it only became the dominant middle-class ideology in Italy, Germany, and parts of South America. Nationalism would remain more important than any other movement in Europe and the United States and in Asian countries.

The middle class in many countries were in favor of a stronger return to imperialism because it had always been profitable for middling sorts such as the merchants and entrepreneurs. It is in part this newfound lust for imperialism that led

to World War II, which would cause even greater problems for the middle class. Once again, men of all classes were fighting alongside each other.

Following World War I the middle class only slowly recovered, having once more taken a great economic blow from 1939 to 1945. Middle-class merchants, importers, and exporters lost great capital after decolonization. The horrors of the war and the ensuing Cold War would finally create an age of consensus for many countries in which fascism and other revolutionary ideas would die out. Legislation would create welfare states in many countries, and this would equalize the classes somewhat. The middle class would only begin to reemerge in most countries in the 1950s.

Women in Central Asia

Soviet Central Asia has always been home to women of many nationalities, including women from the European parts of Russia. The term “Central Asian women,” however, currently includes only women of indigenous and titular groups of Central Asia, such as Kazakhs, Uzbeks, Tajiks, Kyrgyzs, and Turkmens. The discourse over the place of Central Asian women in Soviet society and their emancipation became of primary importance for the early Soviet regime and its efforts at restructuring Central Asian society. Changes in the status of women came to symbolize the successes and failures of Soviet attempts to create a modern communist worker regardless of gender.

In the early years of its existence, the Soviet regime attempted to modernize Central Asia, which it saw as feudal and backward mostly due to its heavy Muslim influence. The overall goal of the Soviet government in all parts of the Soviet Union was to create a *sovetskii chelovek* (Soviet person), a worker, a communist, and an antireligious fighter devoid of any attachments to a clan or region. The Bolsheviks launched a massive antireligious campaign across the Soviet Union in an attempt to secularize the newly formed Soviet society. In Central Asia, Islam was attacked for its alleged hypocrisy and rigid dogmas, and the Soviet government abolished religious educational institutions and the Islamic legal system based on Sharia (Islamic canon law) and *adat* (customary law). The Bolsheviks attempted to create their *sovetskii chelovek* in Central Asia by replacing Arabic script with the more modern Latin script for Central Asian languages, by creating new territorial delineations for the Central Asian peoples, and by establishing new cultural amenities such as museums, available to all.

To support its effort at creating a new and independent woman equal to a man in Central Asia, the Soviet government introduced compulsory education, first at primary level and then at secondary level for both genders. New medical and social welfare networks tailored especially to women’s needs as mothers were established, and the government attempted to involve women in industrial and agricultural jobs. At the same time, legal reforms were undertaken that sought to protect women’s rights by making undamaged marriages illegal and by giving women a share of property after divorce. Along those lines, Zhenotdel, a Soviet bureau for women’s issues, attempted to improve women’s position by abrogating the Muslim practices of arranged marriages, *kalym* (bride price), and polygamy. Zhenotdel workers also promoted a change from the traditional Central Asian dress of *parandja* or *parandzha* (a full-body robe draped over the head) and *chachvan* (a waist-length horse-hair veil) to a more Western dress.

However, the Bolsheviks became disappointed with the successes of their early campaigns at women’s emancipation. By the mid-1920s they began to hope that they could achieve a

➤ THE VEIL AND INTERNATIONAL WOMEN'S DAY

The first major public unveilings of Central Asian women occurred on March 8, 1927, and coincided with International Women's Day, a global socialist holiday. The Soviet authorities chose this day to launch the *hujum* (official policy of unveiling) against what they saw as the subjugation of Central Asian women in an effort to portray their actions in the region as part of a worldwide effort to liberate all women from social and cultural oppression. In the Soviets' eyes, the symbol of this oppression in Central Asia took the form of the head-to-toe horsehair and cotton veil that women were required to don at age ten. Conversely, the Soviets' focus on the veil as a symbol of oppression and patriarchy also elevated the veil as a symbol of resistance among traditionalists. The unveilings took the form of large public ceremonies, sponsored by the Soviet government, in which several thousand women would theatrically discard their veils and cast them onto a burning pile. While the number and the willingness of the participants have since been questioned, such ceremonies became essential in forming the Soviet narrative of liberation.

wholesale revolutionary change if they could change Central Asian women in more radical ways. In 1926 Moscow decided to intensify the emancipation campaign. This new intensive campaign was quickly labeled by the Uzbek word *hujum*, which means "an attack." Although each republic had its own version of the *hujum* aimed at eradicating various subjugating gender practices, its key goal was de-veiling, and its key target areas were the cities where the practice of wearing veil was most visible and deeply entrenched. Party officials, mainly Europeans, saw the loss of veil as a symbol of female liberation from the chains of enslavement in the strictly patriarchal society, a sign of female integration into the public sphere, and the beginning of the civilization and modernization of the broader Central Asian community.

The first large-scale public unveiling took place during the celebration of the International Women's Day of March 8, 1927. Presumably, several thousand women ceremoniously burned

their veils, although the number of women who participated in this event is still disputed. In the late 1920s and early 1930s some women even joined the newly created Godless League to combat Muslim traditions and influences. Surprising to the Soviet authorities, not all Central Asian women eagerly and willingly accepted the de-veiling campaign, and some women opposed it vigorously. Local populations, mostly pro-Islamist and raised on different norms and values, argued that the loss of veil for women meant the loss of Islamic virtue for a female and Islamic identity for the community. Many women believed that the veil protected rather than restricted them, while others feared violence by men if they unveiled.

In the short term, the results of the emancipation campaign in Central Asia seemed very promising. Whereas in 1926 less than one percent of Central Asian women were literate, the literacy rate had increased to 56 percent by 1939. Women were represented in significant numbers in various professions and skilled occupations, and they often entered the market force as paid employees in the public sector. Cultural changes were significant as well. For example, by the mid-1930s it became rare to see a fully veiled woman in urban centers. Although in the countryside many women substituted the veil with large scarves and continued to cover their heads, the first Soviet generation of Central Asian women began to see the veil as old-fashioned and primitive. Many women also embraced the values and norms of antireligious Soviet civil society and became disconnected from Islam.

Other campaigns had mixed results. By the mid-1930s women were involved both in factory work and agricultural production of such items as cotton. However, Central Asian women still lagged behind in public employment compared to other Soviet nationalities. This fact was mostly explained by high birthrates among Central Asian women. In the 1920s when the Soviet government made abortion legal and easily accessible, Central Asian women were too new to Soviet ideology to change their family traditions, which always welcomed many children and especially sons. But in 1936 the policy of the government changed to pronatalist. To support its efforts to sustain and increase the birthrate, the Soviet government improved the existing social

welfare system by establishing new birth clinics, women's health clinics, children's clinics, and daycare outlets; allowing for a mandatory maternity leave of 16 weeks; and offering substantial financial rewards to women with many children. These measures ensured the persistence of high birthrates among Central Asian women despite rapidly growing literacy rates.

Women's Rights

Throughout history, law, religion, political ideology, and custom dictated a subordinate role for women. Many factors led to gradual changes in women's status in many Western and Westernizing nations. These included women's improved educational opportunities, the growth of a middle class, the influence of liberalism with its emphasis on individual rights, and development of social and political movements focusing on human rights, modernization, and, in colonized nations, independence.

Few women could vote before 1900, although many women and men had been agitating for suffrage. Developing a unified movement that involved women from all walks of life was impossible in most countries. Women's movements in Western nations such as the United States and Australia tended to exclude women of color. Fearing internal division, American suffragists acceded to the demands of white Southern women to bar African Americans. Middle-class women were unable to identify with the needs and prob-

lems of the poor. An anti-immigrant bias permeated the American suffrage movement, with some prominent native-born women arguing that their votes would counter the votes of ignorant immigrant men.

The British and American women's suffrage movements served as models for and gave impetus to movements in many nations, especially in Europe and India. By the mid to late 1800s, as a leisured middle class developed, many women joined charitable and other organizations that centered on liberal reforms, including legal reform, education, political participation, child welfare, public health, and suffrage. In the United States and India, public health was a major stimulus. Women with a more conservative background also often seized on temperance as an issue from which to promote women's rights. The Women's Christian Temperance Union (WCTU), founded in 1874, promoted social change to aid family well-being. American representatives visited Australia in the mid-1880s and spread the movement there.

In the United States the suffrage movement had splintered after the American Civil War into conservative and progressive camps. In 1890 the two splintered groups reunited under the umbrella of the National American Woman Suffrage Association (NAWSA). Under the leadership of Carrie Chapman Catt, the NAWSA provided much of the impetus for an international organization that would work for woman suffrage. Delegates from 11 countries, for example, attended the NAWSA annual meeting in 1902.

Women divided over the best ways to achieve their goals. Many women in nations like the United States and Great Britain were uncomfortable with radical rhetoric and tactics. In Great Britain, Millicent Garrett Fawcett's moderate National Union of Women's Suffrage Societies engaged women of all classes. In an opposing camp, the Women's Social and Political Union (WSPU), founded in 1903 by Emmeline Pankhurst and her daughters Cristabel and Sylvia, favored hard-line tactics with its motto, "Deeds, Not Words." Clad in green, white, and purple, they harassed politicians, chained themselves to public buildings, damaged property, marched en masse on Parliament, and, when arrested for rioting, engaged in hunger strikes. Arrests and

mistreatment of suffragettes generated public sympathy. After decades of struggle in Great Britain, some women gained the right to vote in local elections because local government focused on home and family issues, but the Liberal government refused to grant the vote nationally.

American suffragists began to adopt militant tactics around 1910. Harriet Stanton Blatch organized protest marches in New York and established an alliance with the working-class Women's Trade Union League. Alice Paul organized 10,000 women to march in Washington, D.C., the day before Woodrow Wilson was inaugurated as president in 1912 and announced her intention to pressure the Democratic Party until all American women could vote. The NAWSA expelled her in 1915 because they favored a more moderate strategy and believed that universal suffrage would follow after more states granted the vote to women.

World War I temporarily divided the international women's movement over the question of pacifism. In many countries suffrage supporters, like many in the WSPU, suspended their activities in favor of war work. In 1915 pacifists created a new organization, the Women's International League for Peace and Freedom.

The international suffrage movement faced many obstacles. Women in some Latin American countries organized, although the culture dictated gender-, race-, and class-based segregation. The Catholic Church and many politicians opposed universal suffrage. Some governments imprisoned suffrage supporters, yet women pressed on. In Mexico suffrage agitation followed the revolution in 1910, although universal suffrage did not come until 1947 and women were not able to run for office until 1953. In 1929 Ecuador became the first Latin American nation to grant women the right to vote, followed by several of its neighbors in the 1930s and 1940s.

India and Japan were the only two Asian countries with women's movements. In India, a nation with a Hindu majority, Mahatma Gandhi both supported women's rights and enlisted women as participants in protests. However, the Muslim minority opposed women's rights.

The rise of socialism divided the international movement. The Soviet Union gave women equal rights, turned marriage into a civil proce-

dure in 1918, dropped barriers to divorce, and in 1920 became the first European nation to legalize abortion. This led many Europeans to identify socialism with women's suffrage. Socialist women's groups were unable to make common cause in European nations outside of Great Britain and Scandinavia.

Both world wars played a role by bringing many women out of the home and into the workplace. British women over the age of 30 gained the right to vote in 1918, and American women gained the right to vote on the same basis as men in 1920 due in part to their contributions during World War I. In 1928 British women won the same voting rights as British men. Women gained the right to vote in Spain, Germany, Denmark, Sweden, Austria, Czechoslovakia, Poland, Romania, Turkey, and the Soviet Union after World War I.

By 1945 women in many Western nations had some degree of legal and political equality. But women in many developing nations, often illiterate and isolated, made no progress. Their status would not change until after independence later in the twentieth century, if it changed at all.

Chinese Women—The End of the Qing Dynasty to the Early Twentieth Century

By the beginning of the century, rocked by increasing demands from European industrial powers, all aspects of Chinese society were under intense scrutiny. Questions regarding the proper place of women in Chinese society were central

to most of the societal and national issues that the Chinese faced. Many Chinese intellectuals came to believe that the place of women in Confucian philosophy—with its emphasis on maintaining existing hierarchies—had weakened China, making it vulnerable to European intrusion. The Chinese ideal of sequestered women, with tiny bound feet, became a source of embarrassment rather than a source of pride. As an aside, in truth Chinese women had never been as passive as tradition implies. There had been several female rebel leaders during the civil wars that led to the Qing ascension, and there were regiments of women who fought during the Taiping Rebellion. Nevertheless, the law and traditions of China were centered on a strictly patriarchal ideal.

Even during the later days of the Ming dynasty (1368–1644), many scholars supported increasing educational opportunities for women, believing that educated mothers would be able to instill a greater understanding of Confucian ethics in young people. The first Qing emperors had been appalled at the practice of foot binding and the cult of widow chastity, wherein widows were expected to commit suicide and follow their husbands to the grave or, at the very least, to remain faithful to his memory for the rest of their lives. The Qing's attempts to abolish either practice were unsuccessful; indeed, perpetuating them became a point of honor in the name of preserving Han culture until confrontations with European, U.S., and Japanese armies shocked the Chinese into reevaluating China's place in the world.

By the beginning of the twentieth century, the Chinese were in the midst of a tumultuous period of self-examination at every level. The Self-Strengthening Movements of the 1860s and 1870s had focused on adopting Western technology and science while preserving Chinese culture. Students were sent to study in the United States, France, Germany, and Great Britain even as the number of Europeans in China swelled. By the end of the nineteenth century it had become apparent that the approach was fatally flawed. These overseas students did study science, but they were also exposed to European philosophers such as Georg W. F. Hegel, Montesquieu (Charles de Secondat), and J. S. Mill. Exposure to European-based culture inspired close examina-

➤ WOMEN AS PEASANT ORGANIZERS

Although no one would ever describe Chairman Mao Zedong as a feminist, he was among those who believed that China had been left vulnerable to outsiders in part because it had failed to employ the abilities of women. He wrote approvingly:

“As to the authority of the husband, it has always been comparatively weak among the poor peasants, because the poor peasant women, compelled for financial reasons to take more part in manual work than women of the wealthier classes, have obtained more right to speak and more power to make decisions in family affairs. In recent years rural economy has become even more bankrupt and the basic condition for men's domination over women has already been undermined. And now, with the rise of the peasant movement, women in many places have set out immediately to organize the rural women's association; the opportunity has come for them to lift up their heads, and the authority of the husband is tottering more and more every day. In a word, all feudal and patriarchal ideologies and institutions are tottering as the power of the peasants rises.”

tion of the Chinese dynastic worldview and convinced many Chinese intellectuals that their culture needed a complete overhaul. Women's issues were central in the dialogue following Japan's success in the 1895 Sino-Japanese War.

For the first time in China, there was a sense of urgency about gaining maximum benefits from women's intellects as well as their physical labor. By 1900 the anti-foot binding movements were well established. There was a sense that China could be strengthened only if the population as a whole became productive; women with broken or deformed feet were not as likely to contribute to the well-being of their societies. It was

doubted that they could even give birth to really healthy babies. There was actually some truth to the assertion; women with bound feet often developed early-onset osteoporosis and other bone maladies that could in fact have an adverse impact on childbirth and infant health. Strengthening both minds and bodies was considered essential to China's survival. Women lacking training and education were unable to participate in strengthening China. Many Chinese women were active in the reform movements, working closely with foreigners and enthusiastically promoting education for women and an end to concubinage. By 1905 Chinese women were studying in Japan, where they were learning about concepts such as human rights. The idea of educating women caught hold, and schools were started for girls, who were expected to study foreign languages, mathematics, geography, chemistry, and physics in addition to more traditional pursuits, such as calligraphy, home economics, sewing, and music. There were relatively few of these schools—only about 13,000 young women were enrolled in schools throughout China itself—but the impact was great.

Educated young women formed support groups and were often encouraged by parents and family in the movement to abandon the practice of foot binding, which now symbolized traditional restrictions on all young people. Confucianism itself came under attack as a small but influential number of young activists attributed China's failures to the reverence for elders and duties of filial piety imposed by Confucianism. They believed that emphasis on perpetuating the ideals on the past had prevented China from meeting the industrial and technological challenges needed to meet Europeans on their own terms. The New Culture Movement, which emerged during the collapse of the Qing dynasty, had the purpose of destroying the vestiges of Confucianism. An increasing number of women became active in opposition movements. One woman, Qiu Jin, attempted to lead a rebel group against the Qing dynasty and was executed for sedition.

Through the last years of the Qing dynasty, women had become more assertive about securing civil rights. Women participated in ousting the last Qing emperor in 1912 and expected a

role in the new republican government. Led by a Beijing suffragist, Tang Junying, they lobbied for the vote. When their efforts failed, they stormed the government chambers, shouting slogans and breaking windows. They were violently expelled, and their demands were ignored. However, by 1919 opposition leaders such as Mao Zedong had taken the position of earlier literati who argued that China could not be strengthened sufficiently to face the foreign imperialists unless the intelligence and energy of Chinese women were harnessed. The revolutionary movements began recruiting women; the first women were admitted to Beijing Normal University in 1920 as a direct result of the May Fourth protesters.

Chinese women began adopting figures such as Joan of Arc, Florence Nightingale, and Harriet Beecher Stowe as role models. By the time of the May Fourth Movement, both male and female students had become fascinated with Henrik Ibsen's play *A Doll's House*. They admired the heroine, Nora, for her realization that she had a duty to herself that transcended her obligations as a wife and mother. Young men joined women in the cause of feminism, believing that the prevailing Confucian relationships prevented them from developing the individuality necessary to reach their highest potential and meet the challenges of the day. Many educated young men began to refuse to marry uneducated women or women with bound feet.

The Guomindang came to power through a coup in 1927, facing economic upheaval, famine, and eventually civil war. Women's emancipation was featured in the rhetoric of both the communists and the nationalist Guomindang; however, in many ways the intellectuals of the Left were more comfortable with the issues at hand and began training women for leadership roles. Mao instituted a new marriage law in areas under his control—Jiangxi and parts of Hunan—prohibiting arranged marriages if either party objected and gave women the right to initiate divorce proceedings (unless their husbands were on active military status). During the Japanese occupation and civil war the May Fourth ideals persisted, although survival was a more pressing issue for both Chinese men and women. Nevertheless, even under the Guomindang, women

were able to pursue careers in education, law, and journalism. The Guomindang granted women the right to vote in 1947, although the benefits were eclipsed by the Chinese Civil War. In 1949 after the communist victory over the Guomindang on mainland China, Mao instituted a program guaranteeing equal rights to women. The path forward was never smooth, but the idea of equality between males and females endured.

Women's Roles in Developing Nations

Gender and class were variables seldom considered in development discussions during the first half of the twentieth century. Many of what we now consider developing nations were colonies of European powers from 1900 to 1945. Economic statistics gathered by colonial powers ignored women's economic roles, their contributions to the running and functioning of households, and their work in the informal agricultural sector. Included in this was the growing of food for household consumption and informal market trading, which ensured diversity of diet and at times provided funds to pay hut taxes or school fees. Since women were seldom part of the paid workforce, their economic roles were undervalued.

However, notions of class and gender are critical variables when reflecting on women's roles in developing nations. As nineteenth-century imperialism and colonialism became twentieth-century globalization, modernization theories stipulated that gender and class inequalities would decline with increased development. This belief was a major rationale for colonization. The underlying assumption of this approach was that economic growth would create financial opportunities for men and women that would gradually eliminate extreme poverty. Additional assumptions were that gender and class inequalities would be reduced as a result of modernization, training, education, and the incorporation of women into the paid labor force within the global economy.

Instead, colonialism created an exploitative international division of labor and helped situate women into subordinate positions in developing countries as traditional social, economic, and political practices were swept away by European ideologies and economic practices that were imposed on local populations. Recent examinations of class and gender in developing nations revealed systems of inequality and subordination of individuals within societies. An analysis of class and gender exposes both the social relationships between men and women and their varying levels of access to resources and demonstrates the systematic subordination of women and the poor in developing countries. When examined within an international context, this subordination enabled a higher standard of living for women and men of

Women picking tea in the Himalayan foothills, about 1910. (Library of Congress)

➤ GENDER AND DEVELOPMENT

Twentieth-century European sensibilities conceived of men as farmers and women as helpers. This Eurocentric position undermined women's social and economic roles in developing countries. Indigenous women's status as farmers and food producers was undermined, as European administrators introduced only indigenous men to mechanized farming and cash cropping. One illustrative example comes from Uganda, where in 1923, despite the fact that women were successfully growing cotton, the European director of agriculture determined that this export cash-earning crop was too important to be left to women. Within ten years men usurped growing cotton, and women lost access to cash earnings. In order to promote gender equity, the United Nations Charter called for gender equity in 1945.

—Lorna Lueker Zukas

all classes in developed nations and for middle- and upper-class individuals in developing nations.

In general, the social position of men and women in any society is strongly related to their relative economic power. Colonialism and patriarchal kinship systems in developing nations ensured male domination and structured gender inequality as socially normal. Women had no independent access to land, and they had limited access to their own income. Without control of economic resources—that is, access to land or the ability to control monetary income—women were subordinated to men economically, politically, and socially.

As colonial development proceeded, unequal rewards reaped as a result of class and gender domination were touted as natural and deserved. The poor and women, often blamed for their own poverty, were viewed as powerless and without agency. The use of coercion to compel labor ensured the unequal distribution of resources. Economic rewards flowed toward men and members of the upper class, while women and those in poverty eked out survival on a daily basis.

The disparity of wealth and opportunity across class and gender lines was the result of uneven development imposed by colonialism and the ways in which societies accessed—and

were integrated into—commodity markets and the global system of capitalism. Colonial practices and the vast need for labor in newly emergent market economies fundamentally altered existing class and gender relations in developing nations. Dual economic spheres were created. The first was a formal wage-earning sector in which men worked and earned an income. The second was an informal sector in which women operated. The informal sector received less pay and was based on trade and barter. Poor and rural women were expected to work as they had always done, but their right to use land was taken from them. Their work burden shifted as colonial agriculture and industrial development created a pattern of labor migration. This migration took men away from home and into the paid labor force, thereby leaving women in rural subsistence economies as unpaid labor or forced into the urban informal sector. Often men migrated to urban areas to work, and frequently women were not allowed to migrate. If they were allowed, it was only in support roles as prostitutes and companions to keep workers happy or to run illegal beer houses that sold alcohol.

While generally deleterious to the position of indigenous women, colonization enhanced the position of European women in the twentieth century. The status of European women was improved in the colonies: color elevated class status in favor of whites, and even poor white women in the colonies had greater social status than existed for them in Europe. In the colonies, European women advanced socially through marriage and through the opportunity to work and minister to indigenous women. These opportunities were buoyed by the exploitation of indigenous women and men. However, European women engaged in the same paternalistic and ethnocentric behavior, including racism and national chauvinism, as did European men.

Women's oppression and exploitation in developing countries were inextricably bound to accumulation and growth of European and American capitalism and the exploitation and subordination of colonies. The exploitation and subordination of women, nature, and colonies accompanied capitalist development and resulted in uneven development between nations and their populations.

In the first half of the twentieth century a common theme emerged as a result of class- and gender-based analysis. Women and men had differential access to education, health care, and economic opportunity. Women had limited access to the protection of laws and legal recourse, as they were generally considered jural minors. Women were generally seen only in purely relational roles to men: women were only mothers, wives, sisters, and daughters. Class-based systems and poverty exacerbated gender disparities, and poor and disadvantaged women were limited in their ability to participate in later post-colonial national development.

Colonial development helped some countries to modernize and some women to advance, but uneven development left countries poor and robbed of natural resources while enriching the West. Women gained access to employment and remunerated labor opportunities; however, far more women sank into poverty and barely eked out a living, leading to the coalescence of gender and class in the feminization of poverty. Realizing the deep connection between class, gender, and national development, the United Nations Charter in 1945 recognized the principle of gender equity, and this principle was reaffirmed in the Universal Declaration of Human Rights in 1948.

Women's Roles in Developed Nations

Women's roles in developed countries changed rapidly during the early twentieth century. The prevalent belief concerning gender roles at the

beginning of the twentieth century is often described as the ideology of separate spheres. Society, especially in the middle classes, dictated that men were the breadwinners who worked in the public sphere outside of the home, while women controlled the private sphere inside the home in their roles of wife and mother. This idea had begun in the nineteenth century among the middle and upper classes, although lower-class women and widows were unable to conform to this standard. Further challenges to the notion that a woman's only proper role was in the domestic sphere would also come in the form of the suffrage and women's rights movements.

The nineteenth-century ideas of childbearing and child rearing as women's most important functions were further reified by psychological studies and governmental legislation in the late nineteenth and early twentieth centuries. The influential new theories of Sigmund Freud and other psychologists caused parents, especially mothers, great anxiety about child rearing. The idea that a child's relationship to his or her parents was essential to the child's well-being and development made many women feel that they must remain at home or risk damaging their child's psychological state. At the same time, many countries were anxious about population decline at the turn of the century, although these fears regarding decline were greatly overestimated. Nationalism, nativism, racism, and other movements regarding superiorities of countries, races, or ethnicities certainly led to many campaigns to increase birth rates. The two world wars and the loss of life sustained in them continued to feed this hysteria throughout the first half of the century. Governments often saw population decline and families with fewer children as a threat to the status quo. In England and the United States particularly, women were encouraged to have large families, and their status as childbearers was the subject of much governmental propaganda.

Women's sexuality was also strictly regulated in most Western countries. Most nations had effectively banned birth control during the nineteenth century, fearing that it would lead to depopulation and sexual immorality. These same countries banned abortion in increasing numbers in the early twentieth century. Employers

THE NEW WOMAN

In late nineteenth-century Europe, literature began to focus on the internal life of women and their suffering under Victorian mores. These stories often included protagonists who ended their lives or ran away to escape an oppressive relationship to a husband or family. The term “New Woman” was used to describe women who attempted to free themselves from societal norms during the late nineteenth and early twentieth centuries. To protest Victorian standards, they cut their long hair, often bobbing it, and wore shorter skirts or dresses. These New Women attended college or held down jobs to maintain their freedom from oppressive family models. Social and economic freedoms were two main goals of this movement, and independent careers were considered a necessity to achieve independence. These women also embraced sexual freedom. Emma Goldman, Margaret Sanger, and other new feminists began agitating for the legalization of birth control for the purpose of family planning and also to advance the cause of sexual freedom. A lesbian subculture also arose within this context. Sometimes these New Women engaged in other so-called shocking behavior, such as going to dance halls, smoking, and drinking hard liquor. In the 1920s, New Women in America came to be called flappers due to the stylized short dresses they wore.

—Christi McCallum

would even keep single women workers in company-provided housing where they could be carefully monitored. Prostitution was perhaps the best indicator both of a sexual double standard and fears of women’s sexuality. Many countries passed laws allowing prostitutes—but not their male patrons—to be inspected for venereal diseases. Social workers also attempted to keep these women off the streets using a wide variety of methods, including abduction and forced labor.

Despite these factors, many women did not conform to the societal standards. Increasing numbers of women began to work outside the home. While some of these women worked out of necessity, others worked to maintain their independence or to save money for a better standard of living after marriage. Women of different

classes did different work. Women of the upper and middle classes frequently did unpaid charity work, while lower- and middle-class women who had to work for their living usually became teachers or governesses or secretaries as the twentieth century progressed. At the same time, working-class women became factory workers, sales clerks, or waitresses. While many of these women chose to work for pocket money or were forced to work by economic necessity, many female workers became political actors seeking to remedy sexual inequality as much as possible. Some of these were women who sought university education, which had become accessible for women by the early 1900s in most countries; others wished to avoid marriage or desired the freedom to be a part of the suffrage and women’s rights movements that had sprung up during the period from the 1850s through the 1910s.

The women’s suffrage movements originated in the nineteenth century but had grown much larger by the dawn of the twentieth century. The more militant suffrage movements began in the 1900s in many countries. These militant women would disrupt political meetings, break windows, and in some cases burn public property to prove their point. However, militant suffragettes were at the margins of the movement, as most women were moderates who sought reform in a peaceable manner with large-scale marches, public meetings, and pamphleteer campaigns. The suffrage movement was put on hold as World War I threw the United States and most European countries into crisis.

World War I forced many women to work outside the home for the first time. Industrial conscription meant that women were called on to fill munitions jobs and the factory work that men had left behind. Women also became nurses and Red Cross workers on the fields of World War I; small numbers even took up fighting roles in a few countries. Since so many suffragists as well as common women had put aside their previous work and lives to aid the state during the war, most countries granted women’s suffrage by the 1920s. One notable exception was France, which did not grant suffrage to women until 1944.

Aside from suffrage, women’s political and labor activities were varied. Class, race, and many

other social factors led to differing political agendas. Some conservative women were satisfied with the vote alone, while the women of the labor movement continued to be very vocal. Female trade unionists and strikers had many goals, including equal pay (since they made less than the men), better working conditions, and protesting certain job barriers regarding gender (women were banned from certain jobs and others forced them to leave when they married). Many of them continued to use the roles of wife and mother to demand equality, claiming that they needed these changes to care for their families properly.

During World War II, women would once again fulfill many different roles on the home-front and the battlefield; however, this time many refused to give up their jobs at the end of the war. World War II had shown women that there were many inequalities to be corrected. While they could vote and work outside the home, women were not protected from discrimination or harassment, nor could they gain access to birth control in many countries. Only in the 1960s and 1970s would women's issues be addressed more completely.

Feminism in the Middle East

Women's issues emerged as a topic of discussion and debate as Middle Eastern societies modernized at the hand of reformist rulers and social activists early in the twentieth century. Reform-minded rulers introduced women's edu-

ISLAM AND MIDDLE EASTERN FEMINISM

Islam has been part of debates on women's rights in the Middle East throughout the twentieth century, with both reformers and conservatives using Islamic principles to justify their positions. Opposition to changing women's social roles and to abandoning Islam as the primary framework of reference emerged early in the history of Middle Eastern women's activism. In Egypt, Zaynab al-Ghazali founded the Muslim Women's Association in 1935 to fight against social inequality from within a conservative Islamic framework. She encouraged women to play active roles in public, especially in Islamic renewal movements. She herself was an active leader who eschewed motherhood and would not let marriage interfere with her activism. However, she did not dispute the conservative Islamic teaching that a woman's primary duty is to her husband and children.

The tension between secular and Islamic approaches to women's rights has not disappeared and continues to influence debates on women's issues in many Muslim countries.

—Hilary Kalmbach

cation by edict from above, while activists founded movements to improve the position of women socially. Questions about the authenticity of secular approaches to gender equality have constantly dogged Middle Eastern women's movements despite the local women involved in their leadership. Egypt, Persia (Iran after 1935), and Turkey are three Middle Eastern countries in which contexts of modernization led to the emergence of independent feminist movements that were subsumed into the apparatus of centralized states by midcentury.

Women's rights activism rose out of modernization discussions, dominated by Middle Eastern men, of the late nineteenth century. Although reformists of both genders focused on improving women's education and increasing their public presence, they did not encourage women to break out of the traditional roles of wife and mother. In general, these discussions were part of larger efforts to strengthen the nation by modernizing the family, as educated and modern

women would be best able to assist modern and upwardly mobile men in building stable nuclear families based on monogamous companionate marriages. Egyptian nationalist Qasim Amin's book *The Liberation of Women* (1899) is an early work in this vein. In parallel, women in Turkey, Egypt, and Persia were claiming the right to contest the way that both European and local patriarchal discourses portrayed them. Beginning in the 1890s in Turkey and Egypt and the 1920s in Persia, publications written by and for women played an important role in creating and maintaining communities interested in women's issues.

The Ottoman state expanded women's rights, especially with respect to education, after the 1908 Young Turk Revolt. Between 1908 and 1916, women's organizations began to advance both charitable causes and women's issues. Women became active participants in society during the post-World War I Independence War, and the Turkish Republic, founded in 1923, granted women equal legal rights, especially in the areas of education and suffrage. Even with these rights, however, women were not allowed to form political parties, and the organization that they founded instead, the Turkish Women's Union, was disbanded almost immediately after the 1935 Istanbul Congress of the International Federation of Women, supposedly because the state had already granted women all the rights they required.

Egyptian gender reform also began through the state, with nineteenth-century governments attempting—often unsuccessfully—to recruit women into schools as teachers and medical professionals. Women's groups stood in solidarity with men's groups calling for independence from British rule after 1919, yet they were disappointed after independence in 1922 when their cause was abandoned by men, who neither granted them political rights nor supported their increased public presence. In 1923, Huda Sharawi founded the Egyptian Feminist Union in order to improve women's legal rights and opportunities to work and study. The membership of the organization would take part in international conferences and play a major role in regional feminist activity. In the 1940s, a new generation of middle-class women's rights activists in Egypt reached out to a broader portion

of the population and incorporated other ideologies, such as that of class struggle.

Women's organizations in Persia emerged as early as 1906, with numerous groups working for both women's rights and the national cause. During the constitutional period (1909–1920), Persia caught up with Istanbul and Cairo with the opening of women's schools and a teaching college, though women would not enter universities until 1936. The Pahlavi regime addressed women's rights with the 1935 opening of the Ladies Center under Reza Shah's daughters Ashraf and Shams and the 1936 Unveiling Act that required women to unveil in public.

Despite the leadership of local women in the women's movements, critics have questioned the cultural authenticity of feminism, often portraying it as a foreign innovation that would weaken Muslim society. The quasi-feminist policies of colonial administrators such as Lord Cromer in Egypt, who was a staunch opponent of women's rights in Britain, further developed the connection between feminism and foreign power. Authenticity problems and the prominent role that Islam plays in Middle Eastern society explain efforts by women's rights advocates, both historical and contemporary, to engage and challenge Islamic teachings on women instead of calling only on more secularized notions of universal human rights. These issues also partially explain why Middle Eastern gender activists have in many periods refrained from calling themselves feminists.

Masculinities

With the loss of autonomous labor and the subsequent collapse of the separate spheres, men and women increasingly associated masculinity with the ideal of a rigorous lifestyle. The twentieth century brought with it social and cultural transformations that recast men's roles, and the physical and sexual characteristics associated with men changed as well. Where masculinity had once been associated with independent and even savage manliness, as urban centers grew in the twentieth century, women and men interacted more frequently in public arenas, and fewer men worked as their own bosses. As a consequence, masculinity became entwined with the contemporary ideas about civilization and class.

As the relationship between men and women evolved during the late nineteenth century, the conception of masculinity changed as well. The effects of the industrial revolution and the rise of piecemeal factory work ate away at the agrarian economy. Technological advances—such as improvements in transportation, the invention of the automobile, and the need for factory workers to produce it and other goods—created jobs in the cities and reduced the dependence on independent craftsmen and artisans. As a result, more men found themselves working for others and, consequently, having to give up their own autonomy and accept someone else's rules. These changes in turn challenged the masculine ideal of the independent man, since men increasingly depended on someone else's authority—the boss or the corporation—for their livelihoods.

Technology also transformed the way in which people conducted their daily lives. Men who now needed to travel for business—particularly those who visited urban centers—could encounter men and women who frequently interacted and who held modern ideas about the proper role of women. In this way such ideas could be disseminated (and oftentimes attacked) throughout the country as men brought these modern concepts back home. In addition, the influx of immigrants, whose values and traditions differed from native-born Americans, weakened the traditional Victorian household rules that had cast women as the domesticators of the sup-

posed unruly savage male. With single women increasingly entering the labor market and married women spending more time in the marketplace of goods and ideas, men and women spent more time together outside of the home, and the separate spheres that had long divided men and women began to collapse.

Consequently, some men at the turn of the century feared that masculinity was in danger of feminization from the increased exposure to women. With more fathers traveling on business, some worried about the undue influence that mothers might have on their sons, and with more children being schooled in mixed groups and under the care of female teachers, some felt that boys might end up as sissies. As a result of such anxieties, the early twentieth century witnessed the creation of many gender-segregated institutions, including men-only clubs and the Boy Scouts, an organization founded by Lord Robert Baden-Powell in 1907 in England that expressly excluded the participation of females. These types of masculine membership groups arose as a means of maintaining and imposing the Victorian notion of masculinity.

At the same time, Americans started to envision a revised masculine script that encouraged men to take a more active role in the home. Men found personal space just for themselves—hence the rise of the den, the basement office, the workshop, and so on—where they could be at home but be free from the domesticating influences of their wives. Popular magazines and guides urged men to participate in household chores and to be more involved in their children's lives. While few women enjoyed true equality in the home at this time, many men took the first tentative steps toward balancing this reality during the period.

With the heroics and horrors of World War I came a troubled sense of what it meant to be a man. Out of the war arose the so-called Lost Generation, best exemplified by writers such as F. Scott Fitzgerald and Ernest Hemingway, who depicted their male protagonists as tortured and imperfect men who felt alienated by both traditional cultural expectations and postwar attitudes regarding manliness. Unlike their Victorian predecessors who seemed to enjoy certain autonomy as men, many authors of the 1920s depicted

postwar men as tools or victims of a newly mechanized society that had little use for the self-made man of American lore.

After the stock market crashed in 1929, some 10 million men found themselves unable to fulfill one of the basic expectations of that era's conception of masculinity: the ability to provide for the family. The failure of the economic and political system to enable so many men the opportunity to earn a living radicalized many Americans, and the meaning of masculinity changed once again. During the decade leading up to World War II, communism and the ideology of the workers' rights gained a strong foothold in American culture. The most radical interpretations of communism stimulated a modern vision of society in which all men and all women were equals in every sense: politically, economically, and sexually. This construction rejected the contemporary conception of masculinity. Men might be tough or gentle, brutes or intellectuals; these qualities were no longer solely attributed to one gender.

Although most men and women would reject the reality of egalitarian relations between the sexes for decades to come, some modernists and radicals, such as Emma Goldman, actually lived out these theories, eschewing marriage, speaking freely about sex in public, and demanding equality in all aspects of public and private life. Many governments associated sexual radicals with political radicals, and many—such as Goldman—were imprisoned and even deported. However, their ideas eventually percolated throughout Western societies and inspired women and men alike to insist on a fairer society, thus again transforming, little by little, the meaning of masculinity.

Femininity

Femininity refers to what a society wants women to be as well as to what it believes women actually are. The early twentieth century saw dramatic changes and debates about women's rights and roles. Freudian psychology, world wars, advertising, mass media, and celebrity culture were major influences on changing images of femininity. The nurturant femininity of the fruitful mother tended to be connected with nationalism and religious traditions, while the seductive femininity of the single young woman was associated positively with freedom and independence and negatively with fears of uncontrollable female sexuality.

Popular notions about femininity were deeply influenced by Freud's theories throughout much of the twentieth century. Freud claimed that normal femininity was characterized by passivity, masochism, and narcissism, all traits that would be pathological in men. Thus active and assertive women, including feminists and professional women, were often judged as being unfeminine, a viewpoint that restricted women's occupational opportunities during the period and sent many women to therapy. However, Freud's first translator, Joan Riviere, who was also a patient of Freud's and an analyst herself, claimed that femininity or womanliness was always a masquerade, not an expression of an inner nature but an accommodation to a male-dominated society.

In contrast, motion pictures and advertising highlighted changing images of desirable femininity. "America's sweetheart" Mary Pickford and petite Lillian Gish, who played vulnerable innocents who needed male rescuers in silent films, gave way to provocative vamps such as Theda Bara. It was perhaps as much the celebrated allure of Dutch dancer Mata Hari (Margaretha Zelle) more than her espionage activities that led to her execution as a German spy in 1917.

Freer images of femininity appeared after World War I in many countries. For James Joyce, the feminine was embodied in the portrait of his wife Nora as Molly Bloom in *Ulysses* (1922). Associated with sexuality, nature, and the body and antithetical to abstract reasoning, Molly is the voice of the eternal "yes I said yes I will Yes." Daisy Buchanan represents the ultrafeminine flapper to F. Scott Fitzgerald's social-climbing

male innocent in *The Great Gatsby* (1925). She is beautiful, wealthy, charming, and callous to the point of manslaughter. Such fictional femininities are defined through contrasts with dominant male values: Daisy is desirable but immoral; Nora's sexual allure is based on her irrational alignment with nature.

But if feminine women in fiction are often desirable but dangerous, unfeminine women such as Stephen Gordon, the mannish lesbian of Radclyffe Hall's *Well of Loneliness* (1928), are tragic figures, as are the protagonists of Nella Larsen's books of the Harlem Renaissance, which show the difficulties of U.S. women of color in achieving an acceptable femininity within a racist society: tainted by prejudices about oversexed or unwomanly women of color, they are estranged from their own desires. In contrast to these polarities, in *A Room of One's Own* (1929), Virginia Woolf describes both masculinity and femininity ideally melding in Shakespeare's androgyny.

The Great Depression of the 1930s brought images of spunky and independent women to the fore such as the journalists and athletes portrayed in the movies by Katherine Hepburn and Rosalind Russell and by real-life celebrity aviator Amelia Earhart. More ominous was the Nazi regime's glorification of "*kinder, küche, und kirche*" (children, kitchen, and church) as the only concerns for properly feminine women. By World War II the glamorous pinup girl faced posters of Rosie the Riveter, a tough but attractive model of working-class femininity devoted to the war effort in the United States, while Soviet women were similarly idealized as brave workers on tractors.

Not only were the glamorous images on the silver screen beyond most women's reach, but beginning in the 1920s advertising and mass marketing increased women's insecurities about their femininity and promised to sell them products to enhance it. Magazines displayed gleaming appliances to make happy homemakers as well as fashionable cosmetics, perfumes, hats, and gowns that would bring women men's attention and other women's envy.

Throughout much of the globe in the early twentieth century, images of femininity were closely tied to battles over women's rights. In many countries feminist agitation sought equality

➤ JOAN CRAWFORD

Joan Crawford (1904–1977), as shown in this 1928 photograph, is the perfect example of the jazz baby flapper of the late 1920s, the epitome of femininity and worldly sophistication in a decade marked by roaring excess. The heavy affectation and recklessly liberated demeanor of Crawford's late-1920s heroines, invariably depicted as pretty young damsels full of an incredible zest for life and ready to take on the world, made her an exciting symbol and role model for millions of young women who vicariously lived out their dreams through her.

—Carlos Marquez

(Library of Congress)

for women in civic participation, particularly through the vote, and increased access to education and paid employment. New images of women as professionally competent, sexually self-determined, and politically active vied with older images of nurturing mothers, obedient wives, and devoted and patriotic sisters.

Internationally, movements for women's rights produced alternative and embattled femininities, juxtaposing, for example, the seductively cloistered women of Orientalist fantasy with the newly unveiled secular and Islamic women of the Middle East. At the same time, nationalist and anticolonial heroines might either retain traditional costumes and customs or assert modernist independence by switching to Western apparel. Still another archetype filtered from Japan, where geisha entertained and flattered rich, powerful men, setting a standard of femininity that was artistic and decorative rather than sexual or nurturing. In China the Confucian subordinate and obedient wife was revolutionized into the communist heroine, carrying a gun while holding up "half the sky."

After World War II the cultural assumptions that Betty Friedan eventually labeled "the feminine mystique" connected images of domestic femininity with a burgeoning consumer culture, beckoning women to early marriage and suburban child rearing. The discontents of this ideal, as well as its impossibility for many working-class women and women of color, helped spur the Western women's liberation movement of the 1960s and 1970s. This movement attacked symbols of restrictive femininity, whether girdles and high heel shoes, popular Freudian ideology, the sexual double standard, or restrictions on women's education and occupational choices.

Homosexuality

Although same-sex sexual (and ritual) contacts have occurred throughout history, it was not until the mid- to late-nineteenth century that those who were sexually attracted to the same gender were defined as "homosexual." As the construction of homosexuality changed from same-sex behavior to sexual identity, medicalization, particularly in the form of psychoanalysis, joined criminalization as typical societal responses. The twentieth century, not coincidentally, also witnessed the emergence of the homosexual rights movement, as gay men and lesbians began organizing to rescind laws and change medical opinions. Nevertheless, in some Middle Eastern countries same-gender sexual contact still can result in the death penalty and homosexuality was only recently depathologized in Japan, South Korea, and China. Relatively few countries prohibit discrimination on the basis of sexual orientation or sanction same-sex marriage.

The modern homosexual emancipation movement began in 1897, when Magnus Hirschfeld, a Berlin doctor, founded the Scientific and Humanitarian Committee. The group presented a petition to the German Parliament for repealing Paragraph 175 of the Penal Code, enacted in 1871, prohibiting sexual conducts between men. This political movement spread throughout Europe and North America. In the Netherlands, J. A. Schorer, a liberal jurist, established the Dutch Scientific Humanitarian Committee to repeal Article 248, an anti-vice bill that criminalized homosexuality, enacted in 1911. Edward Carpenter, a homosexual activist, was active in the British Society for the Study of Sex Psychology, founded in 1914 under Hirschfeld's influence.

After World War I, the number of homosexual associations such as Freundschaft (friendship) and Klub der Freunde und Freundinnen (male and female) friends clubs increased, while the first state-chartered (albeit short-lived) Chicago Society for Human Rights was established in 1924 by Henry Gerber, who had visited Berlin following the war. There, too, was an increase in gay and lesbian novels, most notably *The Well of Loneliness* written in 1928 by Radclyffe Hall, an English novelist. Banned in many cities and countries, her novel was based on the theories

of Richard von Krafft-Ebing, a German psychiatrist, and Havelock Ellis, an English sexologist.

In contrast to many Western societies, there had been no prohibition of homosexuality in most Eastern societies. In countries such as Thailand, those engaged in same-sex behavior were not considered deviant or persecuted. In Japan, same-sex sexual intercourse was not considered abnormal until at least the late-nineteenth century (under the influence of European colonialism).

The worldwide Great Depression and the rise of fascism in Germany and other countries severely impacted the fledgling gay and lesbian movement, which largely ceased to exist by the mid-1930s. Oppressed liberality, together with the economic crisis, also restricted women's freedom to live and love as they liked. In 1933, Germany, though efforts to repeal Paragraph 175 a few years earlier nearly succeeded, banned homosexual-rights organizations, and Hirschfeld's Institute of Sexual Science was demolished with its valuable collection mostly destroyed. However, communities of homosexuals and social groups continued to flourish in Europe, Asia, and the Americas.

Studies into homosexuality continued throughout the twentieth century. Sigmund Freud suggested that sexual inversion including homosexuality was not innate, but a matter of object-choice in a psychic mechanism, which resulted in the treatment of homosexuals through extensive psychotherapy. However, unlike most medical authorities of the time, Hirschfeld argued that homosexuality originated from prenatal biological factors as did Havelock Ellis, in his book *Sexual Inversion*, which helped frame the arguments of the gay and lesbian movement. In 1948, *Sexual Behavior in the Human Male* had a worldwide impact. Alfred Kinsey, an American biologist, reported that 4 percent of white males were exclusively homosexual throughout their lives, 10 percent of the males were more or less exclusively homosexual, 30 percent had at least incidental homosexual experience or reactions over at least a three year period, and 37 percent of the total male population had at least some homosexual experience to the point of orgasm. Five years later, the companion volume, *Sexual Behavior in the Human Female*, disclosed that 2 percent of the females were exclusively homo-

sexual, between 2 and 6 percent of the unmarried females and less than 1 percent of the married females had been somewhat exclusively homosexual, and 13 percent of the females had homosexual experience to orgasm.

Scientific studies such as those by Kinsey, the development and distribution of new forms of birth control, more permissive attitudes toward sexuality in general, and the efforts of groups courageously demanding social equity for minorities, including lesbians and homosexuals, all underpinned the later advances of the modern feminist and gay liberation movements of the 1970s.

Birth Control and the Birth Control Movement

The term "birth control" was coined by advocate Margaret Sanger in 1914. Birth control is the practice of preventing pregnancy through

THE MALE CONDOM

The male condom, an artificial means of birth control by which the penis is sheathed in a protective material that prevents the sperm from reaching the egg, has been one of the most popular artificial means of birth control since ancient times. Initially made of linen, leather, or animal entrails, condoms were used around the world, including Africa and Europe, for protection against sexually transmitted diseases with moderate success. Their ability to protect against pregnancy was not realized until much later, however.

In the United States, condoms have been produced since 1840 and gained immense popularity after World War I in a campaign to prevent venereal disease. The widespread use of condoms after the war was bolstered by their acceptance by even the most fundamental Christians. Although these groups claimed to accept this form of contraception, it was only due to the condom's ability to protect against disease. As a result, the condom remained one of the most popular methods of birth control well into the late twentieth century, when even better methods were made available.

—*Katherine Ellison*

various methods and devices. Since ancient times, women have employed a variety of processes to avoid, control, and end pregnancy. The most common types of birth control are contraceptives, or methods that prevent the fertilization of the ovum (egg) by sperm, and abortion, the process of terminating a pregnancy. The first half of the twentieth century saw new advances in birth control methods as well as controversy. Birth control remained illegal in many countries, although the period saw the rise of the birth control movement in countries such as Germany, Japan, France, and Mexico. In the United States, distributing birth control and information about birth control was illegal.

The first intrauterine devices (IUD) to prevent pregnancy appeared around 1900 in Germany. Around 1919 Ralph Richter, a German physician, developed the first modern IUD in which a bronze-aluminum wire spiral was inserted into the uterus. When latex was invented during World War I (1914–1918), condoms, dia-

phragms, and cervical caps became more popular. The rhythm method, a calendar-based means of avoiding pregnancy, was also developed in the early twentieth century. Theodoor Hendrik van de Velde, a Dutch gynecologist, discovered in 1905 that women ovulate (during which time they are fertile) only once per month. In the 1920s Hermann Knaus, from Austria, and Kyusaku Ogino, from Japan, independently discovered that ovulation occurs about 14 days prior to a woman's next menstrual cycle. While this information was invaluable to women who were trying to get pregnant, it also provided women with a means to avoid pregnancy.

The Comstock Laws, passed in 24 states beginning in 1873, made the distribution of information and materials considered to be “lewd” or “obscene” illegal. This included not only contraceptives but also the dissemination of information about birth control methods and practices. Although the Comstock Laws are currently still in effect, the ban on contraceptives was declared unconstitutional in 1936, although some state laws restricting birth control and abortion continued until later in the twentieth century.

The movement toward legal birth control in the United States developed during the first half of the twentieth century. During that period, particularly from the turn of the century to the Great Depression, many families could not afford to have more children. Although churches, especially the Catholic Church, opposed contraceptives, some denominations slowly began accepting birth control. Activists such as Emma Goldman and Margaret Sanger sought to educate women about birth control as a way of improving women's lives. Goldman was Sanger's mentor, and they campaigned for reproductive rights and free speech in opposition to the Comstock Laws. Both activists were imprisoned several times for illegally distributing birth control information.

Goldman was born in Russia and in 1885 immigrated to the United States, where she became an anarchist and activist. During the 1890s she worked as a midwife and nurse among immigrant workers in New York, becoming convinced that birth control was the key to providing economic and sexual freedom for women. By 1915 she was frequently lecturing about the move-

ment and published her speeches and essays in her book *Anarchism and Other Essays*.

Sanger was influenced by her mother, who was pregnant 18 times, delivered 11 children, and died of cervical cancer and tuberculosis. She was also impacted by her own experiences as a mother and nurse, working with poor women who suffered from repeated pregnancies and childbirth as well as damaging (and often deadly) self-induced abortions. Sanger was passionate that women be allowed to decide when to be pregnant. In 1914 she published a monthly newsletter, *The Woman Rebel*, that promoted contraception. In 1916 she opened the first U.S. birth control clinic in Brooklyn (New York), although it was shut down by police and she was arrested. Sanger finally opened a permanent clinic in New York City in 1923. She was also instrumental in organizing the National Birth Control League with Mary Coffin Ware Dennett (1915) and the American Birth Control League (1921) that eventually became Planned Parenthood in 1942.

Some birth control activists of the period, including Sanger, had motives other than avoiding pregnancy for legalizing contraceptives. The social philosophy of negative eugenics advocated the use of birth control to stop reproduction among those considered undesirable and dysgenic or possessing inferior and defective genes. The eugenics movement was more than just a philosophy. The United States engaged in a sterilization program in Puerto Rico in 1938 in which around one-third of women of childbearing age in Puerto Rico were sterilized. During the 1920s, Native American and African American women were also targeted for sterilization.

The availability and use of birth control crossed international lines. The birth control movement arrived in Latin America during the Mexican Revolution (1910–1920). The push for birth control in Mexico was more about revolutionary ideology, human rights, and political conflict with the Catholic Church than limiting pregnancy. Mexican women did not embrace birth control for several reasons, including low birth weights, high infant mortality, and adherence to Church teachings.

Sanger traveled and lectured extensively, especially in Europe and Asia. She learned much

➤ PLANNED PARENTHOOD

Birth control advocate and crusader Margaret Sanger founded the American Birth Control League in 1921 and the Birth Control Clinical Research Bureau in 1923 to provide contraceptives and to study the effectiveness and safety of birth control methods. The organizations served a variety of purposes, including educating the American public and organizing and opening clinics to provide women with birth control. In 1939 the organizations merged to form the Birth Control Federation of America, and in 1942 the name was changed to the Planned Parenthood Federation of America. Today the organization is the International Planned Parenthood Federation and has over 800 clinics in the United States that provide birth control services to over 3 million people.

—Kim Kennedy White

from the French about their contraceptive methods during her visit to Paris in 1913. Two years later she visited the Netherlands and learned about the widespread use of the diaphragm among the Dutch. During the 1920s Sanger visited Japan and mentored Japanese birth control supporter Ishimoto Shizue, who went on to become a pioneer and leader in developing Japan's family planning organizations. German birth control advocates also pushed for reform from 1920 until World War II.

Cosmetics and Shifting Beauty Ideals

The female face in Western culture is as much a product of cultural ideals as it is of nature. The use of cosmetics can be traced to the ancient Egyptians and to ancient Greeks and Romans. As a marker of social status, cosmetics not only heightened features but lightened the skin; in particular, a woman's light skin signified her leisured lifestyle and reliance on servants or slaves to run her errands out of doors. Makeup could also conceal the grim realities that crossed class lines. For instance, in eighteenth-century France, aristocratic women and men applied lead-based white cream to their faces and attached small decorative leather patches not just for the sake of fashion but to conceal smallpox scars. In the next century, however, Victorians associated facial makeup of any kind with prostitution.

By the early twentieth century, however, the commercial cosmetics industry in America and Europe used mass-marketing techniques to reach out to women of all classes. The first company, L'Oreal, was founded by Eugene Schueller in 1909 as the French Harmless Hair Coloring Company, followed by American companies Elizabeth Arden, Helena Rubinstein, and Max Factor in the 1910s. These firms were joined by Revlon just before World War II and Estée Lauder just after the war, and their immediate financial success was matched by their power to determine norms of beauty.

Advertisements circulated by the cosmetics industry promised women that through diet, exercise, and the proper use of makeup, they could achieve physical perfection. The advent of cinema and the Hollywood star also impacted early twentieth-century beauty ideals, as teenage and adult women copied the styles of their favorite movie actresses. The vamp actress Theda Bara, for example, inspired a craze for darkly shadowed eyes and reddened lips, connoting the sex-

ually liberated female of the post-World War I era. Max Factor and Helena Rubinstein, who designed makeup for Hollywood actresses, also mass-marketed such new products as mascara to ordinary women who could purchase these products in the dime stores of the 1920s. In sharp contrast to her corseted and pale Victorian predecessor, the carefree flapper bobbed her hair short, tweezed her eyebrows, tanned her now exposed skin, and painted her lips ruby red. World War II surprisingly provided another boon to the cosmetics industry. As American and British women assumed new masculine roles at home or in munitions factories, propaganda reminded them that "Beauty Is Your Duty", and lipstick and nail polish were deemed essential to maintaining a feminine appearance despite grueling work hours. Elizabeth Arden even created a lipstick called Montezuma Red to match the red on the uniforms of women in the armed forces. It should be noted that despite a brief tanning craze in the 1920s, for much of the twentieth century cosmetics advertising still linked whiteness with social superiority, and such middle-class African American magazines as *Ebony* promoted skin-bleaching products.

While the commercial success of the cosmetics industry (today a multibillion dollar industry) illustrates the increased purchasing power of women, feminist historians question the accompanying changes in feminine ideals of beauty as a sign of female liberation. Although the twentieth-century woman celebrated rather than denied her sexuality, the emphasis on her physical appearance may have represented a new form of corset. In addition to cosmetics, the proliferation of beauty pageants, salons, and the diet industry turned women's focus onto the self, distracting them from other political and social goals. However, the cosmetics industry also has empowered women, providing professional opportunities, as several of the most successful companies, such as Helena Rubinstein and Elizabeth Arden, were started by women.

■ Introduction: Cultural Shapers

In addition to the major “isms” of this period (nationalism, imperialism, anticolonialism, fascism, communism, capitalism), other forces shaped culture in this period—most obviously the new media that permitted the rise of mass culture—and what would eventually be recognized as a new “ism,” consumerism. In addition to mass-circulation newspapers and magazines, the development of the phonograph, radio, television, and recorded messages provided new communication media for news, entertainment, and propaganda. Mass production underpinned this system, as it provided the actual devices and the motive for such a communications infrastructure: sales. The growth of the department store in the late nineteenth century directly correlates to the rise of the great daily newspapers, as department store advertisements underwrote those ventures. While some of the new media were nationalized and underwritten by governments, revenues otherwise came from advertising, thus allowing commercial forces to shape radio and television as entertainment media with standardized programming. The advertising industry propelled consumerism, while public relations grew behind the scenes as a power broker and opinion maker, as politicians, corporations, and governments increasingly turned to public relations experts to help shape attitudes of the public and of policy makers. Propaganda, whether to sell government war bonds, demonize military rivals, or strengthen dubious ideological messages of cultural or ethnic superiority, also gained a great boost from the new media and their possibilities. Mass education aimed at social cohesion also became widespread in this period, as did public health campaigns, the settlement house movement to aid dwellers in impoverished urban areas, and a va-

riety of campaigns to stamp out social ills, whether alcohol abuse, narcotics, prostitution, or venereal disease. While visual arts, literature, and performing arts are covered under other topics, the articles that follow examine the general forces shaping culture in this period.

—Fred Nadis

Alcohol and Other Drugs

In the first half of the twentieth century the peoples of the world consumed a huge variety of psychoactive drugs, both legal and illegal: alcohol, nicotine, and caffeinated drinks as well as opium- and coca-based and synthetic drugs. The social context in which these substances were used, whether drunk, smoked, chewed, swallowed, or injected, helps explain their popularity. For instance, the ritual of the Japanese tea ceremony and the English custom of afternoon tea afforded a social significance to the beverage that made it more than a drink. Context also helps to explain the behavior of groups within the larger society. For example, it is difficult to imagine jazz musicians without alcohol and tobacco and perhaps even illegal drugs. Drugs that governments defined as “illegal” could occupy a respected place for certain minorities, such as the smoking of ganja (marijuana) by members of the Rastafarian religious movement in Jamaica and elsewhere.

In the period between the two world wars, the process of drug globalization was far advanced. People around the world enjoyed drugs that had originated thousands of miles away. For instance, millions of Chinese learned to smoke cigarettes. In 1934 a Chinese journalist observed

➤ MYTHS ABOUT NATIONAL PROHIBITION

The most common misconception about National Prohibition in the United States (1920–1933) is that it failed to reduce drinking in the United States. Popular images of bootlegging, speakeasies, and gangsters get in the way of the facts. It is true that in northern cities such as Chicago federal law was only halfheartedly enforced. It is also true that even prohibitionists seemed less concerned with expensive enforcement than with establishing the principle that drinking was a crime. However, despite the numerous violations of alcohol prohibition (similar to the numerous violations of drugs prohibition today), the actual consumption of alcoholic drinks in the United States as a whole fell drastically in the 1920s and early 1930s. Another myth is that Americans alone were eccentric enough to regard prohibition as a solution to the drink problem. In fact, around the time of World War I, many countries adopted a version of prohibition or at least seriously considered doing so. Most famously, under the tsars Russia instituted vodka prohibition, and after the Bolshevik Revolution the new communist regime continued it for several years. Finally, statewide prohibition continued in parts of the United States

New York City Deputy Police Commissioner John A. Leach, right, watches agents pour liquor into the sewer following a raid during Prohibition, 1921. (Library of Congress)

long after the repeal of National Prohibition, and prohibition in localities such as towns and precincts survives even today.

—David Fahey

that villagers who could not identify the nationalist leader Sun Yatsen knew about Ruby Queen cigarettes. Yet at midcentury, globalization remained incomplete. Unlike Americans, few Chinese drank coffee or colas, and by Central European standards their consumption of beer was modest. There are many other examples of the limits to globalization. Russians rarely drank bourbon, and the inhabitants of Kentucky and Tennessee rarely drank vodka. European elites seldom were teetotalers, while Indian elites, other than the Parsis, seldom drank alcohol. Nonelite Indians who drank alcohol consumed toddy-wine or arrack, intoxicating beverages unknown in Europe.

In addition to consumption, production became more globalized. Coffee was grown in Africa as well as in Latin America. In 1933 the Gold Coast (later Ghana) acquired its first brewery. The Dutch East Indies (Indonesia) was a major

producer of wrapper tobacco. Yet globalization of production had its limits. For instance, the growing of opium was slow to spread beyond Asia, while West Africa continued to dominate the production of cocoa.

Tastes also continued to shift. As an example, India had been a major producer of tea for centuries, but it was only in the years between the world wars that Indians became big drinkers of tea. The popularity of tea in India, Russia, and Britain as well as in East Asia made it the most sought-after beverage in the world other than water. During the 1920s cocaine disappeared as a major drug in the United States, while marijuana, introduced from Mexico by migrant laborers, began its popularity. About the same time, many Scotch whiskey distilleries merged in response to shrinking markets. The wine allowance that the French government provided soldiers during World War I encouraged men

from the cider- and spirits-drinking northern districts to remain wine drinkers during peacetime. During World War II Americans lacked access to the green tea previously imported from China and Japan, so American tea drinkers became almost exclusively drinkers of black tea imported from India.

Arguably, the most dramatic stories about for drugs in this period were about efforts to ban or criminalize many of these substances. The United States and Europe attempted to restrict the production of opium and coca to medical purposes, such as for making morphine. Beginning in 1914, the federal government in the United States criminalized narcotic drugs such as opium and coca. Britain outlawed cannabis (marijuana) in 1928. With the help of multinational conventions, the League of Nations restricted the international opium trade. Inconsistently, many European colonial empires profited from the drug trade, although France outlawed hashish in Lebanon in 1926.

China became the world's principal producer of opium, with Shanghai perhaps the world's most important center for opium-related drugs. In the 1930s most of the heroin smuggled into the United States came from China. Although the Nationalist government legislated against opium cultivation and consumption, it was heavily dependent on revenues from opium traffickers, so the Chinese antiopium laws existed principally to appease international opinion. During its wars with China, Japan encouraged opium consumption there but discouraged its consumption in its Manchukuo (Manchuria) puppet state.

The World War I-era attempts to ban the production and sale of alcoholic beverages are well known, particularly national prohibition in the United States from 1919 to 1933 and the concurrent illegal production of liquor and the bootlegging operations that gangsters often controlled. In Russia, under both the tsarist and communist regimes, vodka was outlawed from 1914 to 1925. A few other countries instituted prohibition, and many more restricted the alcoholic drink trades. For example, France banned the anise-flavored spirit absinthe in 1914. Diversion of grain from brewing to baking caused beer consumption in Germany to fall by nearly two-thirds during World War I. Led by Mahatma

Gandhi, the nationalist movement in India demanded prohibition, and in 1949 independent India's constitution declared prohibition of alcoholic drink and habit-forming drugs a national objective. In the end, alcohol prohibition on a national scale survived in only a few Muslim countries such as Saudi Arabia, but most societies recognized the reality that alcohol constituted a serious multisided problem. As one example of addressing the seriousness of its impact, Alcoholics Anonymous was organized in the United States in the 1930s.

During the interwar period, tobacco companies spent huge sums on advertising. Cigarette sales increased, making nicotine one of the world's most widespread drugs. The cinema also glamorized smoking, for instance in the films in which stars such as Joan Crawford and Humphrey Bogart frequently smoked. As early as 1923, Americans purchased 73 billion cigarettes. Even Great Depression poverty failed to depress cigarette demand significantly. Women became smokers in many countries, but men smoked the most. President Franklin Delano Roosevelt reportedly smoked as many as four packs a day. By 1945 the popularity of cigarettes had neared its peak in the United States, and three-quarters of adult males in Australia smoked. There was little public concern that smoking tobacco posed a health risk. As an exception, medical researchers in Nazi Germany worried about the connection between tobacco and cancer. In part for this reason and in part because Adolf Hitler despised smoking, Germany restricted the supply of cigarettes to its troops during World War II. In contrast, chain smoking was a part of daily life in most armies of the time.

Synthetic drugs also were commonplace for the military. It is well known that during World War II Japan provided its soldiers and aviators with the synthetic drug methamphetamine (a derivative of amphetamine), but so did other countries. For instance, the United States supplied 200 million methamphetamine or amphetamine pills and tablets to its troops to overcome fatigue.

The period 1900–1945 witnessed the consolidation of the popularity of Coca-Cola and other caffeinated soft drinks among male and female Americans of all ages, blacks and whites, and all socioeconomic classes. By 1940 Coca-Cola

already was bottled in 40 countries, and World War II decisively accelerated its global expansion: Coke followed American soldiers to Europe and Asia.

The Phonograph as Cultural Shaper

The development of the phonograph—also known as the “talking machine,” gramophone, record player, and turntable—not only impacted entertainment but also shaped culture and the diffusion of music across space and time. At the turn of the twentieth century, for the first time listeners could record and play back music and make personal selections as to what to hear and when.

The term “phonograph” comes from the Greek and means “sound writer.” The first phonograph was developed by American Thomas Edison in 1877 when he invented the telegraph and the telephone. He used a needle to record sounds by etching vibrations onto a cylinder. Edison’s National Phonograph Company manufactured phonographs for home use, although these early phonographs only recorded for a couple of minutes and could not be mass duplicated. These early devices used a floating stylus needle and wax cylinders that began to be mass-produced in 1901. The popularity of the cylinder peaked in 1905, at which time the discs began to dominate the market.

Edison’s phonographs competed with many other companies, particularly Columbia Records and the Victor Talking Machine Company. Columbia Records, founded in 1888 and one of the earliest record labels in the United States, developed a catalog of cylinders that recorded popu-

lar music at the time. In 1891, Columbia’s musical catalog was ten pages long. Columbia Records became the first to produce and sell prerecorded records for home use, introducing a molded brown wax “XP” record in 1902 and the black wax record in 1903. In 1912, the company abandoned cylinders and focused on disc records. The Victor Talking Machine Company was founded in 1901 by Eldridge R. Johnson. The company’s early phonograph and famous trademark logo of a record player attached to a large horn with the famous fox terrier, “Nipper” the dog, listening intently for “His Master’s Voice” is still well known. The horn was rather cumbersome and unsightly to many, and in 1906 the company developed the internal-horn Victrola that sold for \$200.

Phonograph discs proved extremely popular. In 1905 Victor sold 65,591 records, and by 1908 the company sold over 107,000 phonograph players. After some years of economic downturn, sales boomed. Victor sold 125,000 phonographs in 1911, 252,000 in 1912, and 560,000 in 1920.

The 1920s brought phonograph companies major competition from radio and its improved technologies. However, strong phonograph sales continued, especially as consumers had more choices in styles, sizes, and console cabinets in which to house them. By the 1930s, portable wind-up phonographs were readily available. Companies also began to experiment with long-playing records (LPs) in order to make them more appealing to consumers, although the LP was not available until 1948. The 78 rpm (rotations per minute) record was the most popular. The 10-inch (25-centimeter) discs could hold about three and a half minutes per side, and the 12-inch (30-centimeter) discs could hold more than five minutes.

German companies pioneered the music “album.” In 1908 Deutsche Grammophon, founded in 1898, produced a complete recording of the opera *Carmen*; in 1909 Odeon, founded in 1904, released four double-sided discs of the *Nutcracker Suite*. Throughout the next several decades countless recordings were created and sold particularly in the United States, bringing multiple genres of music to households everywhere.

In 1925 Columbia began recording “Vivatonal” records from Western Electric that produced unequalled tone and clarity during the 78-rpm era. Also in that year, Columbia acquired Okeh Records and developed an impressive list of jazz and blues artists, including Bessie Smith and Louis Armstrong. In 1928 the company began recording America’s most well-known orchestra leader, Paul Whiteman. Victor Records, too, recorded famous artists of the time and sold “celebrity” recordings called “Red Seal” records. The records were single-sided until 1923, when they became double-sided.

As discs and phonographs improved in quality, both Columbia and Victor set out to record some of the most prominent folk singers and musicians of the era. In 1928 Columbia executive Frank Buckley Walker pioneered “hillbilly” and country music recordings, including the legendary “Fiddlin” Charlie Bowman. Victor also recorded several legends of country music including Jimmie Rodgers, known for his traditional yodeling style, and the Carter Family, one of the most famous country music groups. Victor first recorded these artists in August 1927 in Bristol, Tennessee, and each embarked on successful recording careers, bringing regional music to the masses.

The 1920s and 1930s also saw the rise of “race music” as U.S. record companies found a new market, particularly in the 1.5 million African Americans who migrated out of the South and who longed for Southern sounds. “Race music” refers to a catalog of recordings in developing genres of African American music: blues, jazz, gospel, and comedy. These “race records” were initially marketed to African Americans, but white Americans began purchasing them as well.

The development of the phonograph brought a variety of musical genres, including traditional folk music, into consumers’ homes, music that they would never have had a chance to hear without these technological developments. Generally transmitted orally, folk music often exists in multiple versions, with its composers generally unknown. Folk songs cover many genres including blues, bluegrass, and country music and reflect the cares and concerns of everyday people. Recordings brought these treasures into homes everywhere and preserved folk culture

➤ THE ROLE OF THE PHONOGRAPH IN DOCUMENTING TRADITIONAL CULTURES

In an effort to preserve and document traditional culture, anthropologists, folklorists, and ethnographers—scholars who document human cultures—used phonographs to record music performances, stories, and myths. Most of the recordings from the first half of the twentieth century in the United States were from Native American tribes, but ethnographers also made recordings in regions such as Haiti, for example, of Hoodoo (“voodoo”) ritual music. Anthropologist Jesse Walter Fewkes was one of the first to make phonograph recordings of traditional cultures, capturing some of the first recordings of the Hopi tribe in the U.S. Southwest and the Passamaquoddy tribe in the U.S. Northeast.

Ethnographers typically spend extended periods among the peoples they are studying. These researchers are participant-observers, as they live among the people, learn the language and customs, and participate in daily life. The phonograph allowed ethnographers to record and preserve these rare and important glimpses into Native American life.

The U.S. Library of Congress American Folklife Center created the Federal Cylinder Project in 1979 in order to share the Native American phonograph recordings that were recorded between 1890 and 1941 with descendants of the tribes. The collection includes more than 10,000 recordings.

—Kim Kennedy White

for generations to come. Many recordings made their way into archives and aided in later revivals of nearly lost styles such as the Jewish klezmer music of eastern Europe.

The cultural impact of the phonograph is immeasurable. As phonograph players and records increased in popularity, availability, and affordability, the average citizen had immediate access to the greatest music of the time. Inhabitants of even the smallest town could listen to the famous Italian opera tenor Enrico Caruso, and rather than traveling across the country to attend expensive theaters, people could enjoy the classical musicianship of Sergei Rachmaninoff from the comfort of their homes. Traditional American

folk music owes its legacy in part to the longevity of phonograph recordings.

Creation of Mass Culture

Mass culture emerged in America as manufacturers, performers, and the media began to locate, create, and communicate with an increasingly interconnected national audience. From the 1880s onward, newspapers, magazines, department stores, stage entertainments, and amusement parks began introducing innovations in their marketing, business practices, and format with the aim of reaching this audience. The mass scope and scale of these forms were expanded

by moving picture shows in the 1910s, broadcast radio in the early 1920s, and, later, network television. Mass culture's growth was facilitated in part by advertisers who sponsored its production and targeted its audiences. This codependent relationship with commerce along with the erosion of local cultures and the creation of new visual and verbal idioms are among early mass culture's defining characteristics.

The first decades of the twentieth century saw the rise of national magazines including *Ladies' Home Journal*, *Collier's Weekly*, and *The Saturday Evening Post* as well as the expansion of advertising agencies such as J. Walter Thompson and N. W. Ayer. The *Post* claimed a circulation of 1 million copies per week by 1909, with this figure rising to nearly 3 million by the late 1920s, while national expenditure on advertising soared and advertisers became increasingly professional, artful, and sophisticated in their techniques.

New industrial processes facilitated mass production, while improved transport links expanded geographical distribution. Manufacturers therefore needed to connect to new markets, and advertising facilitated this exchange. Advertisers provided new revenue for magazines that enabled them to offer more color images, more big-name writers, and often simply more pages. The mix of fictitious, glamorous images and lifestyle journalism presented by the magazines affirmed the advertisers' message that consuming was the key to success, while the colorful, often witty advertisements contributed to the publications' appeal.

Through magazine advertisements, billboard campaigns, and sponsorship of radio programs, branding established Quaker Oats and Coca-Cola as household names and made Uneeda and Kodak synonymous with biscuits and cameras, respectively. As cultural historian Susan Strasser observes, the quality and provenance of an item were no longer assured by personal contact between storekeeper and customer but instead through the brand manufacturer's reputation and advertised guarantees. It may also be argued that the spread of mass-market products displaced local producers, creating an increasingly homogenous nation in which store-bought goods all looked, smelled, and tasted alike.

Advertisement for Uneeda Biscuits, 1916.
(Library of Congress)

Alongside developments in advertising and the media, other forms of culture became increasingly mass-orientated. Starting out as the proprietor of a Boston curiosity museum, Benjamin Franklin Keith built a vaudeville empire that, by the early 1910s, comprised a chain of northeastern theaters. Vaudeville shows typically included dancers, comedians, magicians, and one-act plays. Keith's innovations included the continuous format that ran nonstop throughout the day, scaled-down popular-price performances of successful shows from the upmarket stage, and various measures to distance his venues from earlier variety theater's association with lewd performers and rowdy audiences. These practices attracted passing trade and lunch-hour crowds, tapped into the aspirations of the lower middle classes, and, by conforming to the era's standards of female propriety, made the theater socially acceptable for unaccompanied women.

Keith employed a stable roster of acts in his theaters, thus centralizing power in a manner similar to the Hollywood star system of the 1920s. In other ways too, the motion picture industry developed from—and eventually superseded—vaudeville. The technology developed rapidly, from the unveiling of Edison's Kinetoscope at the 1893 World's Fair through the Lumière Brother's Cinematograph to the large-screen picture houses that were commonplace in American cities by the early 1900s. The motion picture was initially viewed as a technological marvel, and its entertainment potential was only gradually realized.

Edwin S. Porter's 1903 film *The Great Train Robbery*, which introduced narrative by combining connected scenes and striking images to tell a simple story, established the form in which cinema would gain widespread popularity. The 1910s saw the emergence of the two figures central to the silent era, the director D. W. Griffith and the comedian Charlie Chaplin. While such individual pioneers made significant contributions, it was Hollywood's system of stars and genres, its publicity machine, and its production infrastructure that made film the dominant form of pre-World War II American mass culture. Whereas vaudeville theaters were dependent on the physical presence of the performer, a Chaplin movie could reach a truly international mass

➤ A BEHAVIORIST IN THE ADVERTISING AGE

In 1920 a sexual scandal forced John B. Watson, one of the leading psychologists of the early twentieth century and a leader of the behaviorist school of thought in psychology, to leave his position at Johns Hopkins University. He became an advertising man. Watson was an expert in both experimental and applied psychology. Perhaps one of his most infamous behaviorist experiments as an academic involved his research on "Albert B." Watson and his assistants conditioned a nine-month-old boy, via negative stimulus (striking a metal bar near his ear to create a loud noise) to be afraid of a white rat, a rabbit, a dog, a fur coat, cotton wool, and a Santa Claus mask.

After leaving academia, Watson found work in advertising. His theories of human behavior and his way of looking at humans as simple organisms easily conditioned by stimuli such as fear and desire made him an ideal figurehead for the advertising industry. At J. Walter Thompson, Watson quickly became a vice president, working actively on ad campaigns, including for Pond's facial cream as well as Maxwell House Coffee. More significantly, Watson applied his expertise and behaviorist theories to marketing research and sales training. While advertisers likely would have flourished without the help of academic experts in conditioning such as Watson, the association was a powerful one. If advertising seemed to mimic behaviorist beliefs, it is more likely that it was mass culture and its new social realities that influenced the priorities and beliefs of psychologists such as John Watson.

—Fred Nadis

audience, playing simultaneously at as many picture houses as the studio could supply prints to.

As with other forms of massification, selling music to mass audiences led toward homogeneity and the concentration of cultural power. However, the history of early popular music tells other stories too. For example, while eventually assimilated into the mainstream, the emergence of ragtime in the first years of the twentieth century offered a brief window of free expression to African American performers. In the following decades, black bandleaders such as Count Basie and Duke Ellington more fully combined

popularity with autonomy and artistic innovation. Bringing mass entertainment into the private sphere, the radios and record players—popular by the early 1920s—brought new freedom of choice. Historian Lizabeth Cohen has shown that for the working-class residents of Chicago, jazz records and ethnic radio programs, such as Italian-language broadcasts, fostered local communities and specialized cultural practices.

The Great Depression of the 1930s and the onset of World War II engendered responses that demonstrated the power and significance of mass culture. Franklin Roosevelt’s “Fireside Chat” radio broadcasts, Frank Capra’s 1936 comedy *Mr. Deeds Goes to Town*, John Steinbeck’s best-selling novel *The Grapes of Wrath* (1939), and Norman Rockwell’s 1943 *Four Freedoms* series (based on a Roosevelt speech and used to advertise war bonds) all relied on mass media to communicate powerful political messages.

Mass Culture, Advertising, and Propaganda

The term “mass culture” and theorists’ concerns about a populace easily manipulated via the media and advertising did not emerge fully until after the rise of totalitarian regimes in Europe. Similar concerns, however, were triggered by the propaganda campaigns of World War I. While novelist John Dos Passos (1896–1970) depicted public relations and advertising men as among the chief villains of the age, other intellectuals such as Walter Lippman argued that democracy would flounder if experts did not step

in to manipulate and unite public opinion for rational goals.

The public relations industry came of age in the early twentieth century, serving as an elite adjunct of the already-established advertising business. Experts in advertising and public relations such as Bruce Barton and Edward Bernays, borrowing from behaviorist theories of psychology, studied new ways to sell positive images not only of products such as corn flakes but also of powerful clients such as corporations, statesmen, and business leaders.

Radio, which emerged in the 1920s, proved to be another medium, like newspapers, that was ideal for saturation advertising and image making. With Edward Bernays in charge, for example, the American Tobacco Company launched a radio advertising campaign in 1928 in the United States for Lucky Strike cigarettes, and in a two-month period sales increased by 47 percent. Bernays also mounted events to change public perceptions of cigarettes, particularly to make them more appealing to women. When he determined that women did not like the green package of Lucky Strike cigarettes, rather than change the color he slowly persuaded women that green was fashionable by mounting a “Green Fashion Luncheon” and a “Green Charity Ball” and by convincing lead designers to rely more on green. In 1942, however, the green background did give way to the current white.

The connection of advertising, public relations, and propaganda became a topic for debate during the 1920s. In the aftermath of World War I, people slowly became aware of the extent to which Great Britain’s Ministry of Information and Enemy Propaganda Department had orchestrated war news to inflame patriotism and gain allies. Journalist Walter Lippman’s *Public Opinion* (1922), which drew many of its examples from events surrounding World War I, argued that inevitably, individuals live in a “pseudo-environment” clouded by self-interest and misinterpretation and that democracy required a class of experts to guide public opinion and “manufacture consent.”

Edward Bernays, who had served on the Committee on Public Information in the United States that devised propaganda for the U.S. war effort, wrote two books during the 1920s, *Crys-*

► BARTON'S CLIENTS

Bruce Barton (1886–1967) was one of the major advertising and public relations men of the 1920s. Like Edward Bernays, Barton had worked with the U.S. government's World War I propaganda unit, the Committee on Public Information. Following the war, Barton crafted articles and strategies that helped elect Calvin Coolidge president. Barton also consulted with General Motors (GM) and aided the giant holding company in crafting a new public and internal image as a family, aiding GM president Alfred P. Sloan Jr.'s efforts to centralize and unite GM's many holdings.

Barton, however, is best known to historians for his curious effort to turn Jesus into one of his clients. In 1925 Barton published the best-seller *The Man Nobody Knows*. A fervent Christian and fervent booster for business, he attempted to reconcile these two worlds. He repositioned Jesus as a supreme businessman and advertising man. Jesus's message, according to Barton, included

the idea that the greatest sin was to repress oneself. Jesus was cheerful, fit in well with crowds, had a pleasant smile, and knew how to offer great quotes. Barton's long career included the writing of several other religious-inspired books; he also served as a congressman from New York and made a failed bid for the U.S. Senate. Barton remained head of the advertising firm BBDO into the 1960s.

tallizing Public Opinion (1923) and *Propaganda* (1928). In the latter, he remarked that propaganda is the “executive arm of the invisible government” and argued, like Lippman, that such techniques were important to create “order out of chaos.” The possibility of linking modern advertising techniques to politics also was not lost on Adolf Hitler. In *Mein Kampf* (1925), he argued that the public, easily malleable, needed “simple and consistent” messages. The results, as he correctly predicted, “are almost beyond our understanding.” In 1933 the Nazis, after coming to power, created as their first new institution a Ministry of Propaganda.

Radio, Shaper of Culture

Radio, as a communications medium, had its beginnings in the early twentieth century, and its impact on shaping world cultures and populations was significant in the period from 1900 to 1945. As a communications medium, radio took on an industry structure of its own. There were two identifiable segments: the communications medium providers and the communications medium audience. Communications medium providers encompassed all aspects of transmission and content of the varied forms of communications they provided, which included maritime, military, and public communications. The communications medium audience included all cultures and populations of the world capable of receiving radio-based communications. Forms of communications such as propaganda, special events, news, and entertainment distributed by radio would affect people locally as well as

worldwide, thus providing a significant departure from communications in the nineteenth century.

Telephone and telegraph communications existed before 1900 but were primarily communications over hardwire facilities. Signals were transmitted point to point over landline and undersea cable facilities principally by Morse code, but later some signals were transmitted by voice. Guglielmo Marconi, an Italian inventor and electrical engineer, identified and pursued the need for wireless communications and experimented with the transmission of Morse code telegraph signals via radio transmission in 1895. Lee De Forest, a U.S. inventor, developed a three-electrode vacuum tube amplifier by 1906, which provided the technology for radio transmission to include speech and music. The emphasis of radio communications would change to include public communications, which would be point-to-multipoint communications with signals originating from a central radio transmitter and accessible by anyone with a radio receiver. This new medium of radio communications would continue to grow, impact, and shape the peoples of the world in the early decades of the twentieth century.

The first decade of the twentieth century saw maritime communications expanding with the addition of a communications site, called the radio shack, aboard the ships at sea that provided a link for shore-to-ship, ship-to-ship, and ship-to-shore wireless telegraph communications. The safety of maritime shipping increased, which benefited both commercial and military transport of goods. World War I military communications were enhanced through radio and wireless telegraphy, which provided instantaneous communications between military commanders and their subordinates. Radio also served as a governmental tool for the dissemination of propaganda and special events; furthermore, it saw the beginnings of news distribution to major world centers. The events of the war captured the attention and concerns of participants and nonparticipants as well. Radio communications, with increased transmission power and increased receiver sensitivity, made war news readily available to a concerned and antici-

pating world audience. Radio had truly come of age as a communications medium.

The 1920s witnessed increased emphasis on providers' capabilities and audience participation. World War I had instituted technological changes in wireless communications, which enabled providers to reach masses of people simultaneously, a significant improvement over previous hardwire communications. Lower receiver cost made radio accessible to a large majority of the audience base. The providers' response to meet this increased audience availability led to a networking of radio transmission stations, which were usually within countries. However, provider structure, programming, and program content came into question, while many questioned whether broadcasting via radio communications should be a cultural force and whether it should be controlled.

The United States, the Soviet Union, and Britain took different approaches to content, control, and financing. The United States opted for a free enterprise approach, with content being primarily entertainment and news, competition rather than government control, and financing supported by advertising revenues. The Soviet Union favored political and news content with centralized government control and financing. Britain deemed more appropriate a public service approach with mixed programming content, some government control, and financing based on revenues of license fees levied on receiver owners. At this time, the audience had little or no say as to what broadcast content they would receive. In Britain, the British Broadcasting Corporation (BBC), incorporated in 1927, had as its goal entertainment, information, and education of its audience. This approach would expand and become a model for broadcasting in the British empire and elsewhere in the world. Varied locations and forms of radio communications resulted in a unifying effect as well as a cultural guidance in the audience base. The impact and effects of radio communications would significantly rise as the twentieth century progressed.

The third decade of the twentieth century, known as the Golden Age of Radio, saw radio communications and broadcasting proliferate

throughout the world. As a tool for providing news and informational, educational, and entertainment programming, radio broadcasting would immensely affect audiences culturally. Australia, with its vast openness, used radio as the vehicle to provide children with at-home educational training; in addition, Australia's radio broadcasting was fashioned on the BBC model. The Great Depression induced audiences to seek relief from their downtrodden circumstances. Radio broadcasting in the United States recognized this opportunity and incorporated diversity and new genres (westerns, detective stories, dramas, soap operas, comedies, romances, and variety shows) into programming. Serializations such as *The Lone Ranger* provided a weekly opportunity for audiences to follow the adventures of their favorite radio characters. Broadcasts of live performances of variety shows as well as band and orchestra performances made the audience feel like real participants; listening in felt just like being there. Furthermore, in the United States, sponsored programs and later the selling of commercial time became methods of revenue generation and part of the programming packages. This allowed businesses and their products to directly influence the radio audience as well as their way of life.

An example of the effect that broadcasting had on the cultural aspects of the radio audience became very apparent on October 30, 1938, when Orson Welles broadcast an adaptation of H. G. Wells's *The War of the Worlds*. A large proportion of the radio audience believed the drama to be an actual news report of a Martian invasion of earth, and many panicked even though a disclaimer had been announced at the beginning of the program. Another example of radio's impact on daily life occurred on September 3, 1939, when a number of news reports were communicated around the world by radio. First, Britain declared war on Germany. Then, King George VI of Britain notified the members of the British empire that Britain had declared war on Germany; hence, in the face of these events, Canada broadcast that it would stand with its mother country, Britain. However, President Franklin Delano Roosevelt had a message broadcast that the United States would remain neutral.

World War II began in Europe via radio broadcasts; thanks to radio communications, a world radio audience experienced the changing world events as they happened. The world had grown smaller and more connected through the medium of radio communications.

During the first half of the 1940s the world was at war, and politicians quickly recognized the power of radio communications to reach the masses with their message in a timely and cost-effective manner. President Roosevelt utilized radio in his famous fireside chats in order to present his views directly to the American people. Adolf Hitler, Fuhrer of Germany, through his multimedia propaganda campaign during World War II also used radio to convey his vision of what the Third Reich should and/or could be for the German people. Radio during World War II played an important role in both the military as well as civilian segments of the worldwide population. Radio became the backbone of military communications, with new provider equipment supporting the military mission and its specific military audience. Additionally, radio broadcasting provided a crucial link between the military in the field and the home front. Civilian radio broadcasting during this period continued to provide current events, news programming, and expanded versions of the genres of the 1930s. In the decades that followed, much of this format was transferred to the new medium of television. Radio communications and radio broadcasting were indeed forces that significantly motivated and changed world populations and were cultural shapers during the first four decades of the twentieth century.

Disease and Society— The Influenza Pandemics

The influenza pandemics, perhaps the deadliest pestilence in contemporary history, ran rampant throughout much of the world in 1918–1919 and had a tremendous social impact in all world regions. The constant contact between multitudes of troops from various regions of the world in the trenches of the western front during World War I spread the influenza virus, a condition that was exacerbated upon the return of the troops to their countries of origin. The Spanish flu, as it was known at the time, spread in places as far as Australia, South Africa, and the United States to European colonies in sub-Saharan Africa, South Asia, and China. In the course of roughly two years, the Spanish influenza pandemics claimed an estimated 30 million to 50 million lives. The Spanish flu depleted the human organism, particularly the respiratory system, making it vulnerable to other respiratory diseases such as pneumonia. This made it particularly deadly to people with poor health who were also exposed to unsanitary conditions, such as soldiers on the front lines or people living in poverty. However, the disease did not distinguish between gender, ethnicity, class, or religion as it swept throughout the world indiscriminately. The Spanish flu pandemic manifested itself in three major waves

lasting from March 1918 well into June 1920. National, regional, and local governments the world over responded as best they could to quell the catastrophe, often resorting to severe measures or oftentimes futile experiments.

In early 1918 many army camps in the United States began reporting (starting with Fort Riley, Kansas) the outbreak of grippe and/or severe cold among conscripted recruits. The severity of the outbreaks was a cause for alarm, as it led to an increasing number of deaths among the troops. The U.S. Army was responsible for training American doughboys en masse for deployment to the European theater of war along the western front. The reluctance of the federal government to quarantine the troops due to the perceived necessity of sending them overseas increased the incidence of influenza among the scattered army camps in the United States. The outbreak of influenza among the troops in camps and in transit led to the gradual outbreak of the disease in urban centers, particularly in East Coast cities. American soldiers and sailors in transport ships sailing across the Atlantic were prone to the disease, as they were gathered en masse in small areas. Thousands did not survive the voyage to the western front, and those who did spread the disease into Europe.

Gradually, the outbreaks of influenza cases placed a heavy strain on municipal governments across the United States, as they were unable to cope with the increasing numbers of cases and deaths. In cities such as New York, Philadelphia, and Boston an overload in hospitals, morgues, and other medical institutions, due to the large amount of influenza cases, created a situation whereby impoverished people already exposed to the disease and living in squalor died within days. Furthermore, large Liberty Loan rallies to encourage civilian sponsorship of war financing brought large numbers of people together in public spaces, further spreading the virus. The City of San Francisco required the use of gauze masks as a means to quell the disease, imposing hefty fines on those who refused or were caught not wearing them. City governments, while actively intervening by providing medical care and social services, ultimately stressed their own capabilities as city workers, doctors, and nurses became ill themselves. However, many

INFLUENZA PANDEMIC 1918-1919

volunteers filled their ranks as needed in acts of altruism.

The contact between troops from the various Allied nations, colonial troops, and even their Central Powers enemy rapidly spread the disease. Given the increased movement of troops across oceans, the disease rapidly spread into Europe, Oceania, Africa, and Asia. Civilian governments in Europe, much like their counterparts across the Atlantic, had to cope with the increasing amount of people contracting the disease and then expecting their governments to care for them. However, given the exigencies of war and the needs of the troops at the front, European governments of both the Allied and Central Powers did not respond adequately. In the midst of the Russian Revolution and subsequent civil war, droves of Russian troops and civilians on both sides fell ill to influenza. Outbreaks in other world regions, such as Asia (particularly China), Australia, and Africa, were also prevalent, and their civilian governments proved unable to cope with the large numbers of dead and ill. Australia imposed a maritime embargo to cut itself off from contact, but this proved futile because the disease had already spread domestically. Waves of outbreaks ebbed and flowed, causing governments either to

➤ TYPHUS AND WORLD WAR I

Even as the Spanish flu swept across the world in the last year of World War I, typhus had already led to hundreds of thousands of deaths amid the slaughter of the trenches. The squalor and filth of the trenches made these locales ideal for the spread of lice, which carried the disease. Many troops on both the western and eastern fronts were exposed to typhus, leading to the deaths of thousands of soldiers already exposed to shell and machine gunfire. Fatalities from typhus were typically 10–40 percent of the cases of infection. Moreover, typhus was a major cause of death for those nursing the sick, leading to a considerable mortality rate among nurses and medics. From 1918 to 1922 typhus was responsible for approximately 3 million deaths out of an estimated 20 million to 30 million cases. Large populations of refugees and displaced peoples living under unsanitary conditions after the war were also exposed to the disease. However, the use of DDT by authorities to wipe out lice prevented the widespread incidence of death from this disease.

—Abraham O. Mendoza

become complacent when the danger subsided or to nearly panic when it returned.

As the guns fell silent on November 11, 1918, and the armistice ended hostilities, the Spanish flu continued to rage throughout the world. As multitudes celebrated the end of World War I with large parades and celebrations, they continued to spread the virus. The Paris Peace Conference and its continuous meetings in 1918 and 1919 led to the illness of various delegates, most notably French premier Georges Clemenceau and U.S. president Woodrow Wilson. The demobilization of millions of troops back to their countries of origin immediately set the course for further outbreaks as well. However, newspaper reports of influenza outbreaks were subsumed under headlines of peace and the end of the war. In the United States the outbreaks killed an estimated 500,000 to 675,000 people. Britain had an estimated 250,000 dead, and France had approximately 400,000. In Canada approximately 50,000 died, and Australia had nearly 12,000 dead from influenza.

Outside the West, particularly in China and Africa, the disease had already claimed millions of lives given the social and economic conditions of those countries vis-à-vis Europe and the United States. Whole villages in isolated regions in Africa died after exposure to the disease. In the West, those most vulnerable to the disease, particularly the poor, the elderly, and children, already weakened by the dearth of food and widespread destitution, were exposed to the illness, and a significant number died. People with access to better health care were more likely to survive influenza. However, local governments in Sydney, Australia, and in various municipalities in Japan were able to quarantine and prevent the spread of the disease through restrictive health regulations that prevented movement and helped to establish resources for providing services to those who needed it the most. Exact numbers of total dead can only be estimated, but they range anywhere from 30 million to 50 million worldwide, killing more people than World War I.

Impact of Modernization on the Family

In the first half of the twentieth century, many nations around the world emphasized progress as a key social goal. Countries in Europe, Asia, and North America looked specifically to modernization as a way to achieve social progress in this era. In some countries, progress through modernization centered on social reform or new technological tools that improved working conditions and everyday life. In other parts of the world, revolution became an important feature of modernization and social progress.

Modernization refers to the process of becoming modern, or up-to-date. Modernized societies tend to utilize and support the newest tools and ideas available and usually have industrialized economies. By 1900 many states around the world had become industrialized and relied on automated systems for production and transportation systems. With the potential of these new tools to improve people's lives, many around the world believed that the twentieth century would be an era of unprecedented opportunity—or progress—for all.

The changes that modernization brought influenced family life in various ways. In the early twentieth century marriage signaled the beginning of family life in most nations and empires. Often, married couples would continue to live with parents or grandparents even after having their own children, but no matter how many generations lived in a household, marriage was the core of the family. Patriarchy, the idea of the father as the family head, remained an ideal in many Western and Eastern countries. In the Western world companionate marriage based on love began to be more commonplace, while in Eastern Asia and some industrializing parts of the world arranged marriages still dominated.

Before industrialization, many individuals worked out of their homes or had shops near

their homes, and often all family members participated in work efforts daily. As countries became more industrialized and modernized and factories became the primary place where goods were produced—from clothing to meat packing—people's homes became less connected with their employment. In middle- and upper-class families, gender roles reflected this separation between home and work: women remained in charge of domestic life, and a woman's ability to avoid paid employment became a mark of privilege and class status. In lower-class families, however, women worked throughout their lives, doing paid work in their homes or in separate workplaces in addition to their domestic duties.

In the twentieth century women began to work more either before or after marriage, which helped them develop expendable income for leisure activities if they were middle or upper class or provided income necessary to sustain a family. Feminism emerged as an important movement in Europe and the United States as women fought for voting rights and limits on working hours to improve workers' health. In the Soviet Union and China where communist revolutions changed the face of those countries, women were granted at least token equality. Divorce also began to increase in the first half of the twentieth century, although in small numbers, with the emergence of more lenient divorce laws.

The growth of industrialization and transportation networks (such as railroads) in the nineteenth century helped stimulate the expansion of cities in industrialized countries around the world. The availability of both skilled and unskilled labor helped many men and women find jobs and thus be able to afford marriage. Rumors of new opportunities elsewhere led many individuals and families to migrate to cities and even other countries, where they hoped to build new and better lives. While such migration was not new, migrants in the early twentieth century usually ended up in heavily populated urban areas, where low-paying, unskilled factory jobs or domestic labor dominated. Because so many jobs provided low wages, family poverty became a major urban issue. The settlement house movement, begun in Britain and later adapted in the United States, sought to assist lower-income and

➤ FAMILY LIFE UNDER THE NEW IMPERIALISM

Through World War II, much of Africa and Asia remained under foreign imperial rule. These and other less-industrialized regions of the world experienced far fewer changes as a result of modernization than did their imperial rulers. Because places such as India, Kenya, and Ghana were ruled by other nations, railroads and other technological advances did come to these places but in very limited ways.

In the most rural or distant parts of such colonies, far from urban centers of colonial power, family life continued as it had for many years with little influence from the West. Colonization brought missionaries who tried to change indigenous people's lives, to make them more Western and therefore "better" or more progressive. The largest influence perhaps came in colonies where rulers forced colonists into military support roles, such as in Kenya and in western Africa, where the British and the French conscripted men to serve in colonial militaries, particularly during the world wars.

In large cities in particular, African and Asian men and women witnessed the changes that industrialization and modernization brought, sometimes through access to new work opportunities but often simply through increased contact with imperial rulers who were themselves trying to implement modern ideas and tools.

—Tanya L. Roth

immigrant families by providing both formal and life skills educational opportunities. At the same time, the upper-class men and women who led such social reform movements often sought to impart their own vision of family roles to the individuals they helped.

Although most Latin American countries had obtained independence from foreign imperial powers by the mid-nineteenth century, movement toward industrialization remained uneven in the first part of the twentieth century. Some cities, such as Rio de Janeiro or São Paulo, Brazil, experienced economic and social progress similar to that in Europe or the United States. In more rural areas, however, preindustrial family patterns continued, with an emphasis on family labor to produce farm goods. Many families in Latin American countries remained under the influence

of Western nations such as the United States as well as the Roman Catholic Church. Because of Latin America's heavy export trade to the rest of the world, relationships with former European imperial powers such as Spain persisted to varying degrees. Through these relationships, Latin Americans gained exposure to emerging Western ideas of gender roles and family structure. The construction of the Panama Canal and the U.S. acquisition of Puerto Rico further increased American political and cultural influence.

Two key events of the first half of the twentieth century made particularly strong impacts on family life. World War I and World War II disrupted family life temporarily as men (both fathers and sons) left home to fight for their countries. Women entered jobs previously held only by men in order to continue the nation's economy during wartime. The absence of men from the home front for periods of up to seven years especially changed women's and children's lives. During the two world wars, women's employment rose dramatically as women entered wartime production work and helped to build all sorts of support materials for military use in national defense. At home during the wars families also learned to make do with fewer resources, but in general, despite the absence of husbands and fathers, family life continued. Marriage ages lowered during the wars, particularly World War II.

The deaths caused by the wars reshaped family life for many years. In Britain after World War I writers spoke of the "surplus one million" women who would never marry because of the number of men killed by the war. After the dis-

ruptions these wars wreaked on family life, many nations sought to reestablish traditional family ideals. Women's roles as mothers and wives grew to be of immense importance to various countries' efforts to make up for the population loss of war and to return to normalcy. By the end of World War II, although modernization had changed the family in many ways, many nations around the world harkened to the importance of the traditional family structure founded on marriage. In the first half of the twentieth century families gained greater access to contraception or family planning knowledge, and in many areas of the world family sizes had begun to decline. Women continued to move into the workplace before and after marriage, while children moved increasingly out of paid jobs and spent more time in school and youth activities instead.

■ Introduction: Colonialism in Shaping Society and Culture

The creation and collapse of empires is not a phenomenon of modern history alone but instead is a theme revisited time and again throughout human experience. By the end of the nineteenth century, European powers used their burgeoning industrialization as an excuse for collecting colonies in the hope that the usurpation of raw materials would maintain eco-

nomic growth. Meanwhile, colonies also served as a ready locale for undesired members of society, as was the case for Australia, for example. Nations were also motivated by those reasons for empire as well as enhanced national rivalries in the face of British success.

The most obvious location of European imperialist rivalry can be seen in the events surround-

ing the scramble for Africa, which took place between 1871 and 1912. In this short period of time, the bulk of the African continent was occupied and claimed by the British, French, Belgian, Dutch, Portuguese, and German governments. Native populations, which were largely devastated by military, missionary, and economic intervention in their social, political, and cultural lives, had no influence on the partition of their lands. Driving the desire to possess Africa was not only the hope that immense natural wealth would result but also increasingly racist pseudo-scientific beliefs in the superiority of white people over people of color. The theory of social Darwinism (which was never put supported by Charles Darwin) and a variety of religious doctrines were used by imperialist politicians to justify white rule in Africa and throughout the non-European world. Such ideologies prompted theories of Orientalism, which classified knowledge about native peoples in ways that essentialized their cultures and made their societies easier for colonial governments to control. That coupled with the military superiority of Europeans made successful resistance to imperialism difficult to mount.

The expansion of Europeans throughout the globe turned a European political scuffle in the Balkans into World War I in 1914. With the defeat of the Ottoman empire in 1918 and its subsequent dismantling, along with the defeat of Germany and its loss of imperial prestige in the Treaty of Versailles (1919), Britain and France gained even more colonies particularly in the Middle East, where they had already exerted great influence for several decades.

In Palestine a new major European colonial movement—Zionism—had been flourishing, with British support, since the late nineteenth century. From the 1880s, Jews from Europe had acquired land and established settlements with the goal of creating a Jewish nation-state in Palestine, the ancient land of Israel. When the British took control of Palestine at the end of World War I, Jewish settlement increased, but that caused major strife in the region because the vast majority of the population consisted of Arabs who feared losing control of their nation to European colonists. Although the British tried to curb Jewish immigration in 1939 after serious

strife between Jews and Arabs left them fearful of losing access to petroleum reserves in the Middle East, the monumental destruction of European Jewry during World War II coupled with the superior military organization of the Jews in Palestine and open support from the United States led to the creation of a Jewish state in 1948. For Jews, the founding of the State of Israel was a relief from a world riddled with anti-Semitism, but for most Middle Easterners this was a new form of European colonialism at a time when many colonies were calling for independence.

—Nancy Stockdale

Colonialism in Africa

While there are examples of colonialism that date back to the ancient world, and while colonial empires in the Western Hemisphere played an integral part in Europe's economic development from the fifteenth through eighteenth centuries, the term "colonialism" in reference to Africa is generally used to refer to the expansion of European power and influence in the late nineteenth century, during a time often referred to as the Age of Imperialism. The demands of the industrial revolution placed increased pressures on European nations to secure sources of raw materials, markets for manufactured goods, and new opportunities for investment. European nations looked outside their borders to secure what they needed for continued prosperity.

As a result of industrialization, European nations were no longer interested in negotiating with sovereign African states but rather sought to exert direct political and economic control of resources and markets. Moreover, by the end of the nineteenth century, industrialization had given European nations the military means they needed to ensure their interests were served in Africa. The last barrier to European expansion into Africa fell in the 1850s when European medical advances decreased the impact of malaria. However, by 1880 there were no real indications of Africa's susceptibility to European power. An overwhelming majority of Africans enjoyed a sovereign existence, and so what happened in the next 20 years was in many

ways surprising and sudden. Between 1880 and 1900, 90 percent of Africa was occupied by Britain, France, Germany, Belgium, Portugal, Spain, and Italy; only Ethiopia and Liberia escaped colonization.

Nineteenth-century Europe was characterized not only by the profound economic transformation caused by the industrial revolution but also by the development of nationalism often expressed in an exaggerated promotion of a country's prestige. European nations sought not only economic and political security but also recognition, and overseas colonies became status symbols for their influence. The influence of nationalism cannot be underestimated in the expansion of the colonial system. Colonies not only ensured necessary elements for continued economic development but also determined status within Europe's community of nations.

The other element in Europe's new relationship with Africa centered on the moral justification for colonialism—the civilizing and Christianizing mission, the so-called “White Man's Burden.” The moral justification centered on the belief that colonialism elevated the colonized, that European control of Africa would provide the economic, political, and social infrastructure necessary for the development and modernization of the continent and its peoples. Such attitudes exhibited the overt ethnocentrism that is inherent in colonialism. But if the social and religious justifications for European colonial control over Africa were insufficient, the words of French poet Hilaire Belloc illustrate the European attitude toward Africa on the eve of colonization: “Whatever happens we have got; the Maxim gun and they have not.”

As European states sought to extend their presence in Africa, concern arose among the European powers of the potential for conflict that the “Scramble for Africa” could cause. So to decrease the potential for clashes, representatives of all major European powers met at the Berlin West Africa Conference in November 1884 to determine the “rules of the game.” There were no African representatives in attendance. The Berlin Conference proved effective in keeping European conflict to a minimum during the era of colonial expansion, but now the practical questions of how to oversee the new colonies

quickly emerged. Generally, two systems, indirect and direct rule, were established to administer the colonies. The British implemented the policy of indirect rule, developed by F. J. D. Lugard, high commissioner of the British Protectorate of Northern Nigeria. Britain ruled through existing tribal authorities where possible. These authorities continued to oversee the population using traditional systems and customary laws; the British simply administered from above. This system required the least effort and cost and preserved African political traditions, thus having moral benefits as well as practical ones. In areas where strong, highly centralized states existed, indirect rule preserved traditional tribal community structures, but in areas where cultural identities were more complex and fluid, the British had to create authority structures where none were thought to exist. As a result, colonial powers created artificial communities and authority structures that necessitated rigid ethnic identities and sowed the seeds for future conflict. Generally, however, the system of indirect rule left indigenous customs and practices undisturbed—although the activities and demands of Christian missionary organizations did not. Where there were no obvious indigenous political elites, the British created them, and where local elites proved uncooperative, the British removed and replaced them.

Those local elites who cooperated were rewarded, as the British confirmed their authority and often unwittingly removed restrictions on a chief's power by abolishing traditional systems of checks and balances. Local authorities were expected to maintain order, collect taxes, and organize labor and military drafts. They were under the supervision of British district officers who served as intermediaries between local authorities and the central colonial administration. While the British system of indirect rule appeared to function with little disruption of traditional authority, in actuality, local authorities often found their legitimacy challenged as they were seen as simply implementing and enforcing British desires and as being complicit in the maintenance of a colonial system that denied opportunities to the African population.

Most other European powers initially used direct rule, a model of governance most associ-

ated with the French. Using the model established in France, the French divided up their colonies into districts, assigned a French commissioner to oversee them, and appointed a governor-general to administer all the districts in a single colony. Colonial administrative boundaries were often established to divide up powerful tribes to weaken their resistance to French policy, and powerful African leaders were undermined or replaced with more cooperative figures. The French commissioners were responsible for tax collection, labor and military drafts, overseeing public and social works, acting as a local judiciary, and enforcing the decisions of the governor-general. Africans had access to positions in the lower levels of the French bureaucracy but generally had to be considered assimilated into French culture and fluent in the French language. The French generally had two policies for the African population, assimilation and association, and they vacillated between the two throughout the colonial era. Assimilation of the African was the stated goal of French colonial policy as they sought to transform the African in the Western image. This policy rested on the assumption of the superiority of French culture above all others and to a certain extent on the legacy of the Enlightenment's ideals of the universality of man. For those not capable of assimilation, the French established association, a kind of collaboration with locals. As the colonial era wore on, the French increasingly embraced elements of indirect rule. Direct rule was too costly, required too much manpower, and was not as effective in dealing with local customs and communities.

After World War I most colonial powers implemented elements of indirect rule, although the timing varied throughout the continent and was often determined by the nature of the colonies' populations. The colonial system was expanded as administration extended into rural areas usually under the direction of a district official and small native army under European command. Colonial policy matured, and while the development of natural resources continued to be a focal point of the system, colonial authorities attempted to extend social services and opened up some limited mobility to Africans within the colonial bureaucracies as a

growing Westernized and educated African class emerged. In some colonies the expanded opportunities for Africans within the system were met with segregation and increased race consciousness among the European settler elite. But ultimately the impact of the two world wars resulted in the transformation of the colonial system into a type of "sacred trust" that was to be managed by Europeans until Africans were capable of self-government. Labor unions and young political activists in Africa, influenced by socialism, began pressuring the colonial systems to change. By the late 1940s colonial occupation was seen as costly and was increasingly criticized; by the 1950s African nationalist movements started sweeping the continent.

There has been great debate about the impact of colonialism on Africa. In the grand scheme of the continent's history, the colonial era lasted a short time—less than a century. Most early accounts of the colonial period were written by Eurocentric scholars who emphasized the positive impact of colonization by focusing on the civilizing mission, the introduction of new technology and medical advances, and the onset of modernity. But the era of African nationalism resulted in the emergence of Afrocentric and Marxist analyses of the colonial era that were hardly sympathetic to the European point of view. Generally, these studies concluded that the colonial era interrupted Africa's natural development and condemned the continent to stagnation and continued exploitation. It is clear that African nations emerged as artificial creations of colonial powers with populations often burdened with rigid, artificially created ethnic identities. While European political institutions were established with the intent to develop forms of representative democracy, the lack of African participation and access to those institutions during the colonial era undermined their legitimacy even after the colonial system was dismantled and Africans took control of the executive, legislative, and judicial branches of government.

In the arena of social impacts, those who promote the benefits of colonialism often refer to the introduction of modern medicine and the new economic opportunities and modern amenities provided by urbanization. Such arguments are often countered by the criticism that these

benefits were limited in number and access. Other critics comment on the negative impact of colonialism on women, who often found themselves pushed into domestic activities and out of traditional economic activities and social roles.

But the topic most debated on the social and cultural legacies of colonialism is that of the impact of Christianity. The introduction of Christianity and its adoption by some Africans introduced new social tensions into African society. Converts adopted European behaviors and dress, gained access to modern medicine and European education, and as a result abandoned traditional practices. African societies split into two groups: a small, Christian European-educated Africa elite and a larger traditional, predominantly rural and illiterate group. The adoption of Christianity meant undergoing Westernization and resulted in many Africans being alienated from both cultures. They were no longer traditional, and in fact often openly condemned anything traditional, but neither were they allowed, despite their dress, education, and behavior, to be European. It was in this transformation that the seeds of colonialism's dismantling were planted. For it was out of the Westernized, European-educated African elite that movements for Africa's independence would grow. The colonial era came to an end with the emergence of independence movements in Africa. The century of European domination and colonialism was an extremely important era in Africa's history, one whose legacy continues to impact and direct the continent's present and future.

African Cities in the Age of Colonialism

Africa contained vibrant urban societies long before European colonialism. For centuries, cosmopolitan towns such as Mombasa on the East African coast or the inland Sahel city of Timbuktu linked Africa with the rest of the globe through long-distance trade. Beginning in the late nineteenth century, African cities underwent a period of momentous change as a result of colonialism. In less than a century urban populations grew exponentially, many new cities emerged, and diverse cultures from the African continent and abroad struggled for a place in an expanding urban environment. Colonial policies encouraged Africans to come to the city as migrant workers but failed to recognize them as equal members of the urban social order. As a result, cities were some of the most contested spaces in colonial Africa.

By the beginning of the twentieth century, nearly the entire African continent was under European colonial rule, with economics serving as the primary motivating factor. In order to develop and exploit the continent's agricultural and mineral resources, infrastructure and new centers for trade and administration were constructed using massive amounts of African labor. The European-controlled colonial governments passed new taxes and used forced-labor tactics to compel Africans to join the workforce. In colonies with large white settler populations such as Rhodesia and South Africa, the best farmland was taken from Africans, leaving many with little choice but to look for work away from their homes. Coercive policies across the continent forced thousands of workers, especially young men, away from their homes and families to towns and cities.

COLONIAL NAIROBI

Founded as an administrative capital in 1899 when the Uganda railway reached central Kenya from the coast, Nairobi grew to become the principal center for European settlement in East Africa. Africans were encouraged to come to Nairobi as casual laborers and not permanent residents. With only a few thousand residents at the beginning of the twentieth century, Nairobi reached a population of 267,000 by the end of colonial rule in 1963. Nairobi represented the oppressive policies of a society dominated by European settlers. Housing was segregated, and in many cases Africans were not allowed to own homes within the city. Pass laws were enacted by the 1930s, requiring Africans to have permission to leave their rural homelands and restricting families from settling in the capital. By 1939 there was a large gender imbalance of nearly eight men for every woman in the city. These cruel policies ultimately created a source for violent resistance to colonial rule. By the 1950s disenfranchised urban residents supported populations in

Street in Nairobi, Kenya, about 1900. (Library of Congress)

the rural forests of central Kenya in a four-year guerrilla war against British rule that would ultimately bring an end to colonialism in Kenya.

—Matthew Carotenuto

Existing trading towns grew in size. Completely new cities such as Lusaka and Johannesburg emerged as well, built to house the growing mining industries of southern Africa. Other smaller cities, such as Arusha in northern Tanzania, were built as garrison towns to house the new colonial administration and demonstrate the force of European authority. On a continent that was overwhelmingly rural before the twentieth century, population shifts occurred; by 1920, an estimated 4.8 percent of Africans lived in cities, with that number rising to more than 14 percent by 1960. Dakar, for instance, grew from a meager 18,000 residents in 1908 to an estimated 383,000 in 1960. During the same period, Leopoldville (present-day Kinshasha) expanded from 5,000 to 420,000 residents.

The massive growth of African towns during the colonial era had drastic consequences. Population levels outstripped the infrastructure of most cities, creating difficult living conditions for residents. Wages for African workers in towns were low and unequal, and countless workers were denied advancement due to discrimination on the basis of race. Many cities, such as Cape

Town and Dar es Salaam, were segregated and unequally developed, with policies enacted to discourage families of urban laborers to join them in the city. In various colonies vagrancy laws were passed that made it a crime to be unemployed in a town away from one's rural homeland. Overall, the view from the colonial administration's perspective was that the city was a place for Europeans to live and Africans to work.

With concentrated populations of frustrated workers, cities became focal points of resistance against colonial rule. In most colonies, direct African political representation was not permitted; however, this did not stop Africans from organizing mutual aid societies, sports clubs, and labor unions that became mediums for voicing discontent. After 1945 when the majority of the continent began the slow struggle for independence, political movements and conflict against the colonial state often manifested themselves in the cities. Large-scale labor strikes were common in the 1940s and 1950s as Africans fought for greater rights. Political protests, sometimes met with violent resistance, were also prevalent in the cities, where urban populations were instrumental in

winning the struggle for independence from European colonial rule.

Colonialism in Africa South of the Sahara

In Africa south of the Sahara from 1900 to 1945 the foundations of European colonial rule during the twentieth century were established. After 1885, commercial relations with Africa were replaced by direct political control. During the Africa Conference in Berlin in 1884–1885, the different European nations determined that a territory on the African coast could only be recognized as a protectorate if there was a real occupation. During the following years, numerous treaties were concluded with rulers and local chiefs that permitted the European powers to establish protectorates. There were various struggles on frontiers between France, Great Britain, and Germany; between Portugal and Great Britain; and between Germany and Great Britain. Treaties between the European powers fixed new frontiers. African populations resisted, but they were opposed to an enemy armed with modern guns while the African populations only possessed arrows and bows. Colonial rulers had to negotiate with native rulers, who required reforms and a sharing of power. Former traditional authorities tried to maintain their power as participants in the British system of indirect rule or as collaborators in other colonial systems.

Colonial administrations were developed as a reaction to local systems and metropolitan (British, French, German, and so forth) policies. They varied, although their goals were similar. Above

all, colonial administrations had to avoid financial burdens and minimize their staffs. Everywhere, a dual system could be found with a central administration in the capital, composed of the governor, high police, army officers, councilors, lawyers, and civil servants. This level executed directions and orders received from Europe. On a secondary level, local administrations existed that included African political institutions.

The British colonial system was characterized by its administration of British colonies as separate countries, ruled by a governor nominated by London and under the control of the Ministry of Colonies. The governor was the head of the central administration, composed of an executive council, a committee that had only little power, while a local legislative council introduced laws that had to be accepted by the governor. The African elite sought to be represented in the executive councils and in later years required public elections of its members. The basic principle of local administration, indirect rule, was introduced in many territories with varying successes. It was based on the assumption that African kings and local chiefs could best rule African populations. From 1900 to 1906, Lord Lugard introduced this system in northern Nigeria. The region was known for its powerful rulers and numerous civil servants. This system was accompanied by direct taxes that were often rejected. The system also was introduced in the Gold Coast (today Ghana), simultaneously in Sierra Leone and Gambia. Indirect rule required the division of a territory into several provinces that were administered by a white resident under the control of the government. Each province was divided in districts administered by district officers who were Europeans responsible to the resident. The district officers supervised and counseled local kings and rulers. If local rulers were ready to collaborate there were rarely problems; instead, there was a relationship of mutual respect. European civil servants did not learn local languages and thus depended on interpreters. The Africans themselves undertook unpopular measures (e.g., to raise taxes) to the satisfaction of the British rulers. Local rulers gained privileges and were inclined to satisfy their foreign rulers even if they neglected the interests of their populations.

OTA BENGA

For a brief time in 1906 the most popular exhibit at the Bronx Zoo was a 23-year-old Bachichiri pygmy named Ota Benga. While he was free to roam about the zoo as he wished, Benga was encouraged to spend much of his day in the Monkey House, where he would entertain upwards of 40,000 patrons a day by shooting his bow and arrow, showing off his sharply filed teeth, and playing with an Orangutan. Reflecting the realities of the time that often dehumanized human beings, Benga was purchased out of slavery in the Congo Free State in 1904 by American explorer Samuel Phillips Verner and was brought to the United States for a special display of the world's tribesmen at the St. Louis Exposition. Opting not to return to Africa, Benga stayed in the United States and eventually ended up under the care of the Bronx Zoo. Despite his popularity, his exhibit was quickly shut down due to protests from both anti-Darwinists and a group of vocal African American ministers. Benga was later relocated to Lynchburg, Virginia, where he lived until his death on March 20, 1916, when, sadly, he took his own life in the woods just outside of town.

With the racism common to ethnological exhibits of the day, Ota Benga, from the Congo, was displayed at the Bronx Zoo in 1906. (Library of Congress)

The French colonial system was different. The French united colonies into federations; for example, the federation of French Western Africa was composed of eight colonies. A general governor supervised the federation; separate governors administered each colony. Even if these civil servants were very powerful, their decisions had to be approved by the French gov-

ernment, and all laws were enacted in Paris. A council of largely European civil servants met once a year. The French also pursued a policy of assimilation, allowing some African subjects to become French citizens with all their rights and duties. Colonies were considered parts of the French overseas territories. Assimilation took place in four Senegalese towns, whose

inhabitants were French citizens, Catholic, and educated in schools similar to those in France. Moreover, blacks and mixed people could attain high positions in state administration, the army, and commerce. These four towns also elected a deputy for the French National Assembly. Assimilation permitted educated Africans to attain an equal status with the French.

Outside of these four towns and until 1939, only 500 Africans became French citizens. This was a result of the selection criteria: aspirants to citizenship had to be proficient in French, had to have worked for ten years for the French, and had to have served in the army. Assimilation also presumed the superiority of French culture over African cultures. Africans had to abandon their traditional cultures, a fact that would later lead to the movement of *négritude*, which favored the idea of African identity.

In other French colonies, a system of association was implemented: Africans were subjects with limited rights and numerous duties (taxes, military service, and forced labor). A colony was divided in cercles, subdivisions, and cantons. African rulers had limited power but had to levy taxes, muster soldiers, and collaborate with colonial administrations.

The German colonial empire (in Togo, Cameroon, and parts of Southwest Africa and East Africa) existed only until World War I. These colonial administrations depended on the form of settlement or on local conditions. Congo was the only Belgian colony in Africa, which experienced different phases of administration: first, as the property of the Belgian king (until 1908); second, as a territory administered by the Belgian state with the assistance of local rulers nominated by the colonial power (until 1919); and third, as a territory subject to larger administrative units that required Belgian civil servants.

The Portuguese colonies in Africa were Angola, Mozambique, Guinea-Bissau, Sao Tome, and Principe and the Islands of Cape Verde. The Portuguese introduced forced labor and assigned territories to commercial societies with unlimited power. They sent thousands of young people to Africa and practiced a system of apartheid. English and French colonial territories saw the end of colonialism mainly during the last years of the 1950s and the beginning of the 1960s,

whereas the Portuguese colonial system finished in the 1970s.

Literacy in Sub-Saharan Africa

Though often assumed to be nonliterate and to rely solely on oral tradition, many African societies were using writing—or at least were in contact with it—at the beginning of the twentieth century. Some ancient scripts, drawing back to the earliest times of the spread of writing such as the Ethiopic script, were likely in use. The Arabic script, introduced along the routes of the spread of Islam on the eastern coast and in West Africa since the eighth century, was used not only for writing Arabic but also several African languages such as Malagasy, Swahili, and some West African languages. Its influence went far beyond the literate centers, especially through the magical uses of the written word. The Roman script, introduced by Western missionaries and colonizers, also played its part. In Africa, Roman script had long been used for European languages for political and commercial purposes by colonizers as well as by Africans, such as the Kongo chiefs in present-day Angola, beginning as early as the sixteenth century. African languages also were gradually written down in the Roman script through a process implying language description and codification. Alternatively, a series of inventions of African scripts occurred in the nineteenth century (the earliest known is the Vaï syllabary script, invented around 1833) and continued in use in the early twentieth century.

This general pattern can be described as restricted literacy, referring to the fact that the uses of literacy were limited to parts of the population. This changed with the establishment of

THE BAMUM SCRIPT

In the very last years of the nineteenth century, King Njoya in western Cameroon invented a script for the Bamum language. The first system was logographic (each sign representing one word) and evolved to a syllabary in its last version of 1903. If the report of the invention follows the general pattern of African script invention, with the genius inventor having an inspired dream, what makes the Bamum case stand apart is that it led to an effective if short development of literacy in the script. Njoya had a political desire to strengthen its uses. He initiated the mapping of his kingdom and the writing down of its history, developed administrative uses of the script, and created a body of literature. The whole project came to an end in the 1920s when the colonial authorities (French by that time) decided to close the schools where the script was taught and dismissed Njoya, who died in 1933.

“Indigenous” African scripts have been viewed as instances of an authentic African aptitude to invent writing. Against this approach, Konrad Tuchscherer has defended a view that acknowledges the creativity of the inventors while taking seriously the amount of evidence that suggests a diffusion of the idea of writing and the borrowing of some features from other scripts. His genealogy of the Bamum script locates it in a cultural environment where Islamic culture was present, links Bamum invention to the presence of Vai script in

"King Njoya teaches the first symbols of his script to leading citizens" (translation of top line of the picture). (Courtesy Palace Museum, Foumbam)

this part of Cameroon, and suggests that Vai script itself has one of its sources in the Cherokee syllabary. Countering vexed debates on authenticity, such an approach to African scripts testifies to the insertion of the continent in global circulations of knowledge and arts as well as creative human agency in combining borrowed and local forms.

—Aïssatou Mbodj-Pouye

European colonial rule at the turn of the twentieth century. At first, writing served as a means of taking hold of cultures and peoples through the use of maps, lists of ethnonyms, reports, and so forth. Once areas were settled, colonial administrations relied on a ruling technology to which writing was integral. Bureaucratization required the systematic recording of persons and belongings, and the use of documents in courts implied that individuals had to keep written pieces of evidence throughout their lives. Colonial power, especially indirect rule, provided a strong impulse for the writing down of local histories. In some areas this work had already been undertaken by scholars literate in Arabic, but the colonial enterprise differed from these existing chronicles by its more immediate political implications.

Along with this process of imposition, literacy was more deeply rooted into African societies through schooling. Although schooling had been introduced earlier—often by missionaries—in the first half of the twentieth century, it became a common agenda of the colonizing governments. A growing need for auxiliaries in the administration and for skilled and literate manpower in the workplace favored the development of elementary schooling, though in contrasted ways under the different colonial rulers.

In French West Africa until the Brazzaville Conference (1944), metropolitan and colonial systems were distinct, with the latter providing restricted access to postprimary schooling. This pyramidal system aimed at creating a small elite of civil servants through schooling in French. At the same time, an attempt at controlling Muslim

education was made by establishing *médersas* (madrasahs), with the first French *médersa* in West Africa founded in 1906. Though of limited enrollment, this initiative was important in setting up a system that was to be later taken over by African Muslims besides enduring traditional Islamic learning.

The history of education in the English-speaking colonies departs from the French-speaking colonies on the issue of language. The linguistic policy of the British ruler relied on both local languages and English. Debates arose on the choice of the vernacular. A lingua franca, such as Swahili in Kenya, could be imposed on communities whose mother tongue was different, such as the case of Kikuyu, thus creating intense discussions. English often became the written language of the new African intellectual along with a few African languages whose description had progressed.

The uses of African languages in print relied upon the ongoing work of linguistic codification, and during the early twentieth century the main issue was that of standardization. An important step in that direction was the publication in 1927 by the International Institute of African Languages and Cultures in London of *Practical Orthography for African Languages*, proposing an alphabet suitable for all African languages.

Even in Ethiopia, a country that long stood apart from European colonization and had its own age-old literate tradition, drastic changes occurred during this time. Religious and historical literacy in Geez was challenged at the end of the nineteenth century by the written use of Amharic, which was written in an adapted form of the Ethiopic script. But it was not until the development of modern schooling in the twentieth century that written culture in Amharic really started. For other Ethiopian languages, competition arose between the Ethiopic, the Arabic, and the Roman scripts, but literacy in these languages remained scarce.

When first introduced, schooling was often resisted, avoided, or confined to minority groups; however, it eventually made its ways into African societies. It provided the basis for a wider development of literacy. In colonial settings a class of intermediaries developed, and in

the 1930s an entire African subelite emerged. The diffusion of a print culture and the development of sociability through newspapers and reading circles was a prominent cultural feature of this group, which would play a major role in the various nationalist movements following World War II.

Colonialism in Africa North of the Sahara

Morocco's loss of independence in 1912 was a final step in the wider division of Africa north of the Sahara, also known as the Maghrib, by European powers. Previously, European penetration and colonial expansion had eliminated the Ottoman claims over much of Mediterranean Africa beginning with France's 1830 invasion of Algeria through the 1881 declaration of a French protectorate over Tunisia and then again in Italy's 1911 invasion of the long-coveted Libyan coast. Resistance and European "pacification" campaigns continued, but by the time of World War I, European powers had claimed the whole of the Maghrib.

➤ MESSALI HADJ (1898–1974)

Messali Hadj was a prominent early advocate of independence for France's North African colonies. Born into a family of artisans in Tlemcen, Algeria, he served with hundreds of thousands of other young colonial soldiers in France during World War I. In the postwar era, he returned to Paris as part of a new wave of colonials seeking work in metropolitan France. He married a French woman and, in the mid-1920s, emerged as the leader of the communist-influenced Étoile Nord-Africaine (North African Star), the first group to openly advocate independence for Algeria. Forced underground, Hadj's movement in the 1930s reflected its leader's growing split with Marxist thinking and rising interest in Pan-Arab nationalism. At about the same time, it began to spread from its metropolitan seedbed back into Algeria itself. Capitalizing on the opening provided by the French Popular Front's call for reform in Algeria, Hadj spurred the nationalists forward and founded the Parti du Peuple Algérien (Algerian People's Party) in 1937.

Despite being repeatedly arrested through World War II, Hadj saw his influence among the masses grow, sometimes at the expense of rival opposition figures and groups. Near the war's end, wary French colonial officials deported him to the French Congo, helping to galvanize the popular opposition that erupted in the bloody Sétif Uprising in 1945. Released from internment, Hadj began a new phase of political and clandestine military organizing, creating the Mouvement pour le Triomphe des Libertés Démocratiques (Movement for the Triumph of Democratic Freedoms) and, in the mid-1950s, the Mouvement National Algérien (Algerian National Movement). Deep divisions between the latter and the emerging Front de Libération Nationale (National Liberation Front) distanced Hadj from the main currents of the revolutionary struggle, and he remained in France after Algerian independence until his death in 1974.

—James P. Mokhiber

As colonial policies, administrations, and societies in North Africa took shape, they assumed a variety of forms. In the Moroccan protectorate, Resident-General Hubert Lyautey trumpeted a supposedly more enlightened colonial policy inspired by French military doctrine in the wider empire, experience in the Tunisian protectorate, and emerging British “indirect rule” policy in Africa and Asia. Lyautey's application of “association” policy sought to preserve a shell of “traditional” indigenous institutions and officials through which the French would rule. In this way, policy in French Morocco was framed as a reaction to conditions in Algeria, where the powerful settlers—“French” in status but drawn from diverse Mediterranean roots—dominated as they sought to radically remake their society along European lines. A similar settler-dominated society began emerging in Libya, where in the 1920s and 1930s the government promoted more intensive colonization on what the fascists would come to celebrate as Italy's “Fourth Shore.”

In many ways, however, the effects of European colonial control were similar across North Africa throughout the early twentieth century.

These included the accelerating alienation of land in favor of “modern” agriculture and European interests, an emphasis on crops (such as citrus and wine grapes) intended for export, and the development of a transportation infrastructure focused upon bringing agricultural products and valuable raw materials to the coast. At the same time, the colonial powers maintained tariff regimes that favored industrial imports, undermining North African artisanal production. The establishment of unequal tax and credit regimes enshrined the privileges of the European population, as did prejudicial legal systems that sometimes divided indigenous North African groups on ethnic or religious grounds. Even where they high-mindedly claimed to preserve “tradition,” colonial cultural policies transformed North African arts, religious practices, educational systems, and languages. Growing European-style cities, sapping the power of the remaining old medinas, drew an exodus of rural North Africans into their orbit while simultaneously testifying to the power, wealth, and confidence of the imperial powers through their design, experimental architecture, and colonial monuments.

During the twentieth century, colonialism also reoriented North Africans' exposure to global forces and thought. Some North African students began seeking the education unavailable to them at home by turning to Europe, where Leftist intellectuals and Arab nationalist newspapers circulated through the cafes. Thousands more sought work in European fields, mines, and factories, sending crucial remittances home and mixing with labor organizers and communists. In the 1930s the global economic depression affected North Africans of all classes, revealing their connections to world markets even within protected colonial spheres. Over 300,000 North African conscripts and volunteers joined other French colonial troops on World War I's battlefields, while thousands more crossed the Mediterranean to replace European workers.

With the return of peace, new forms of resistance and organized opposition to colonialism took a more discernible shape, especially as political and economic conditions became more acute. Many mark this transition by pointing to a trio of events in 1930—the staging of grandiose celebrations of the centennial of the French conquest of Algiers, the announcing of the divide-and-conquer Berber *dahir* in French Morocco, and the holding of a Christian Eucharistic Congress in Tunis—that outraged a wide range of North Africans at the time.

However, anticolonial resistance during the interwar period sprang from diverse and deep roots and took many forms. Elite-based movements, inspired by prewar groups such as the Jeunes Tunisiens (Young Tunisians) and Jeunes Algériens (Young Algerians), continued to call for greater equality and political participation for North Africans within reformed colonial systems. The Paris-based Maghribi workers' organization Étoile Nord-Africaine (North African Star), founded in 1926, drew on the alienation experienced by expatriates in the metropole to sharpen its demands for independence at home. In eastern Libya, local religious leaders and forces—particularly the powerful Sanusiyya order—drew on their political authority to tenaciously challenge Italian rule into the interwar period. Elsewhere, North African Islamic reformers, tapping deeper into international intel-

lectual currents like the Salafiyya movement, decried popular local Sufi “superstitions” and sought to undercut European claims to superiority through their call for religious and cultural revival. Labor crises and political organizing drew others into the nationalists' ranks and parties, including Habib Bourguiba's Neo-Destour (New Constitution) party in Tunisia. The bloodiest resistance against the colonial powers occurred in Morocco's Rif Mountains, where Abd al-Krim's revolt evolved into a sophisticated republic that the French and Spanish strained to put down in 1926. In the face of this increasing organization, rising expectations, and recurring crises, the foundering of the French Popular Front government's plan for reform in North Africa in the later 1930s appeared particularly meaningful.

The repercussions of the ensuing World War II were deeply felt in North Africa. The aura of stability that the colonial governments had long labored to create was undermined by the quick Nazi defeat of France in 1940. Both the 1942 Anglo-American invasion known as Operation Torch and tank battles in Libya and Tunisia brought the war to North Africa, while the wider conflict took hundreds of thousands of Maghribi soldiers and laborers to Europe once again. The war also brought propaganda and a new wave of political ideas to North Africa, sharpening political discourse as the Allies overturned the Vichy French and fascist Italian regimes there. Amid such political fluidity, nationalists' aspirations began to crystallize, and they issued manifestos and reconstituted themselves into new parties, such as Morocco's Istiqlal (Independence) party in late 1943. International events, such as the founding of the Arab League and the creation of the United Nations, further fed nationalists' hopes. A premonition of the tumultuous struggles and days to come, however, came on V-E Day in eastern Algeria when celebratory parades turned into anticolonial protests and riots, which the French government harshly suppressed. Indeed, the postwar era would usher in a new period of upheaval as North Africans struggled to achieve independence and began to confront the challenges of the postcolonial world.

Colonialism in the Middle East

The modern Middle East is a product of various movements with long-lasting consequences to its current geographic composition. With both internal and external actors and influences, colonialism in the Middle East diverged from other related conquests throughout the globe. Regional and nonregional powers played a crucial role in the mapping of the modern Middle East and often delineated the region's governments and regimes. With a number of imperial colonial powers—namely the Ottoman Empire, Britain, and France—shaping its current geographic makeup, most countries came to be independent nation-states during the early and latter parts of the twentieth century, predominantly during the decolonization era of the 1940s and 1950s.

As an imperial power, the Ottoman Empire (roughly 1300 to 1922) encapsulated much of the Middle East under a pluralistic mode of economic and political control spanning present-day Iraq, Kuwait, Syria, Lebanon, Palestine, Egypt, Jordan, Saudi Arabia, Oman, Bahrain, and parts of Algeria. Ottoman expansion began as early as the fourteenth century with the conquest of Hungary and the Balkans around 1350. Countering the force of the Byzantine Empire, the Ottoman Empire became a tenacious force, one that would dominate the Arab world for four centuries only to be toppled by its dissolution during World War I. Although lacking a cohesive system of governance, the empire's primary mode of control was the instillment of administrative systems of control over much of the Middle East.

The decline of Ottoman rule throughout the region can be attributed to the rise of Mamluk rule in major metropolitans, namely Egypt, Iraq,

and Syria; the rise of Wahhabi Saudis in central and eastern Arabia; and the insubordination of the Bedouin tribes. The empire's slow dissolution throughout the nineteenth and early twentieth centuries resulted in two interrelated outcomes: the solidification of Arab states throughout its former territories followed by the subsequent European colonization of strategic countries primarily by Britain and France.

The dissolution of the Ottoman Empire created a surge of European interests in the region. This is evidenced by its division and subsequent devolution into smaller countries, as promulgated in the Treaty of Sevres in 1920 by key European powers, primarily France and Britain. Although difficult to pinpoint the precise time frame of European colonization of the Middle East, the French colonization of Algeria in 1830 symbolized the beginning of a long-standing resistance to European occupation and control.

Accordingly, the nineteenth century marked the emergence of European colonial expansion and annexation of North Africa and subsequently the Middle East. This was evidenced by the French colonization of Algeria in 1830 and Tunisia in 1881 and the conquest of Morocco in 1912 as settler states. This was followed in 1882 by the British occupation of Egypt, formally declared a colony during World War I. This was followed by the occupation of Syria and Iraq under the French and British mandate system.

Following World War I, the League of Nations mandate system authorized the occupation of territories formerly under the dissipated Ottoman Empire by European Allied Powers. Consequently, the formation and imposition of the Mandatory system resulted in the distribution of former Arab Ottoman provinces to Britain and France. Its primary function was to facilitate the transition of newly formed states following the collapse of the Ottoman Empire and countries emerging out of centuries of European colonization, particularly Africa, into independent nation-states. Territories that were deemed in need of assistance on the road to full independence were placed under Class A Mandate, to be administered by the League of Nations. For the Middle East, former territories emerging out of the Ottoman Empire were divided among two European powers in 1920. Whereas Iraq,

► DRAWING UP BORDERS—ETHNIC MINORITIES IN THE INTERWAR MIDDLE EAST

The mapping of the Middle East by successive colonial powers resulted in the creation of nation-states out of otherwise multiethnic territories. The oppression of ethnic minorities gave strength to various secessionist movements that continue to the present. Arbitrary borders drawn based on economic divisions for colonial powers rather than along ethnoreligious and linguistic lines created a proverbial powder keg of tension, especially among groups initially promised territory and later left out. Kurds, Druze, Berbers, Assyrians, Yezidis, and others found themselves in hostile environments detached from their brethren who now fell under the jurisdiction of other countries and governments, which would come to create scenarios that would resonate throughout the Middle East. It is therefore of no surprise that since the creation of these states, minority issues have continued to plague the development of cohesive multicultural, multireligious, and multiethnic states. Due to the imbalance of power in the Middle East left by the withdrawal of European powers, previously disenfranchised groups sought alternate means of obtaining national recognition and inclusion in an otherwise predominately Arab society. This saw the Assyrian quest for recognition and autonomy in Iraq followed by their indiscriminate massacre, dubbed the Simele Incident, in 1933; Berber demands for recognition in Morocco; and various Kurdish demands for autonomy including armed resistance in Iraq, Iran, and Turkey.

—Sargon George Donabed and Shamiran Mako

Palestine, and Transjordan were mandated under British rule, Lebanon and Syria were the sole responsibility of France. To further colonial control over the region, the Sykes-Picot Agreement of 1916 awarded Britain and France control over post-Ottoman states to ensure greater economic control of newly emerging Arab states by the two contending European powers.

Accordingly, the Balfour Declaration of 1917 became an instrumental British policy stance in favor of the creation of a homeland for the Jewish people in Palestine. The declaration conformed with the immigration policy of the Zionist movement, which sought the return of

Diaspora Jews to Palestine. The rise of anti-Jewish sentiment in Europe created a surge of Jewish immigration to Palestine during the latter part of the nineteenth century and the early twentieth century. Although the initial immigration wave appeared inconsequential, Jewish immigration was met with fervent discontent and animosity from Arab inhabitants following World War II and resulted in the creation of the State of Israel in 1948. Thus, colonial powers were key actors in this historic endeavor for strategic, geopolitical, and economic reasons.

Economic and political incentives were the bedrock of European interest in the Middle East both prior to and following the collapse of the Ottoman Empire. At the onset, European economic and political influence in the region was solidified by the promulgation of specific treaties known as capitulations by Ottoman officials that bestowed European merchants with special privileges, including the right to be governed by their home state laws while administering business endeavors in the region. Guilds were formed to sustain European mercantilism, which ensured a steady market for European exports, manufacturing, production, and services.

The nineteenth and twentieth centuries witnessed an increase in economic activity between Europe and the Middle East. Investments in infrastructure development and economic liberalization in Egypt, Syria, Lebanon, and Iraq ensured a constant flow of trade in goods and services and the revitalization of the manufacturing industry between the two continents. The discovery of oil in Iraq and Iran intensified the scope of European colonial interests in the region, namely with the establishment of the Anglo-Persian Oil Company, renamed the Anglo-Iranian Oil Company in 1935 and later the British Petroleum Company. Similarly, Britain's long-standing economic ties with Iraq, both pre- and post-mandate, were directly related to the discovery of Iraqi oil fields during the late 1920s, which led to the establishment of the Iraq Petroleum Company, formerly the Turkish Petroleum Company. In addition, economic and political endeavors also facilitated a transformation in social and religious structures of the territories in question, particularly with the increase in missionary activity stimulated by Western societal contact and influence.

The search for political and economic independence from West European powers resonated throughout various anticolonial movements in Africa, Latin America, and the Middle East. The decolonization period of the 1950s witnessed the demise of colonialism in the Middle East, a movement parallel to the rise of Arab nationalism in the region. The early termination of the British Mandate in Iraq led to its independence in 1932, with the appointment of King Faisal I of Hashemite ancestry, while Egypt gained its independence in 1936. Syria and Lebanon gained independence from France in 1945 and 1946, respectively. The struggle for independence from France for Morocco, Tunisia, Libya, and Algeria was a pivotal process for many North African states, often leading to violent revolt and great death tolls throughout the 1950s and 1960s.

Colonialism and Nationalism in Southeast Asia— Cultural Aspects

Colonial control of Southeast Asia, which by 1914 was almost complete, impacted the people of the region not just politically but also economically and culturally. Diverse peoples were brought together to form colonial entities. Economies were run for the benefit of distant colo-

nial powers and for foreign business concerns, seldom for the betterment of indigenous populations. Southeast Asians reacted to this foreign presence on a cultural level in a wide variety of ways. Ironically, Western cultural influence may have been instrumental in ending colonial rule.

Initial resistance to imperial rule was seldom successful, due in large part to the great imbalances in terms of technology. Clashes between Southeast Asian and European armies were generally one-sided affairs, as, for example, when Dutch forces armed with modern weapons destroyed much of the Balinese aristocracy in 1908. Subsequent resistance was often aimed at restoring an idealized version of the precolonial order. Messianic figures would draw on rural discontent and lead poorly armed followers against the colonial authorities with the apparent goal of turning back the clock and reestablishing traditional kingdoms and religious institutions. A late example of this was the unsuccessful Saya San rebellion in Burma (1935–1937). Saya San, a former monk, used religious symbolism—including the construction of a makeshift palace—in an attempt to establish a Buddhist kingdom free from British control.

Saya San's movement was essentially backward looking. The Southeast Asian individuals and organizations that would eventually succeed in ending colonial rule would look to a different set of inspirations. They would also be motivated by the idea that European rule was neither inherently benevolent (as colonial apologists argued) nor inevitable. The 1899 Boxer Rebellion against the Western presence in China evoked sympathy throughout Asia. The 1911 revolution against the Manchu dynasty and the activities of Sun Yatsen and the Guomindang Party pointed to the possibility of reforming corrupt autocratic Asian regimes in order to meet Western challenges. The Indian National Congress, under the leadership of Mahatma Gandhi, provided similar encouragement, especially in the years before World War II, whereby some real progress was being made in winning over political power from the British. Grassroots organization, noncooperation campaigns, and cultural authenticity were all elements of the Indian national struggle that were of interest to other Asians. The most spectacular of the Asian

influences was that of Japan, which in 1905 scored a military victory over Russia. Not only was European invincibility called into question, but a model was also provided of an Asian country building up its economic strength, modernizing its society, and defeating foreign armies and navies while retaining its Asian identity. Such sentiments would remain strong as Japan expanded its Asian sphere of influence. Japan saw itself as the natural leader of Asia, and many Southeast Asians were initially comfortable in seeing Japan in this role if it meant an end to European domination.

Modern Southeast Asian nationalists were also heavily influenced by their colonial rulers, often having attended European-style schools, speaking European languages, and practicing the European professions of engineering, teaching, journalism, and political activism. Such concepts as democracy, rule of law, constitutional government, secularism, socialism, and communism fed the minds of young Southeast Asian leaders who questioned colonial rule and wondered whether Western ideologies were universal or whether they applied only to Europeans. Woodrow Wilson's Fourteen Points, which called for the self-determination of subjected peoples, was, as Ho Chi Minh discovered while petitioning the 1919 Versailles Conference, not intended for colonial subjects. Western talk of justice and equality stood awkwardly in opposition to the reality of a colonial system that classified, organized, judged, and even paid its subjects using racial criteria. Despite the overwhelming advantages possessed by colonial authorities, which allowed them to crush uprisings with relative ease and to jail and exile opponents, Southeast Asian nationalists persevered and organized mass and cadre movements along generally Western lines. Their aim was to seize control of the modern administrations created by the Western colonial powers rather than to restore a lost indigenous past. When Western technological and military superiority were rendered meaningless by the Japanese invasion of Southeast Asia in 1941–1942, nationalists were able to take advantage of the situation either by cooperating with the Japanese or through armed resistance in anticipation of an Allied victory.

Stepping into the power vacuum created by Japan's surrender, Southeast Asian nationalists put forward new national identities that would eventually be the basis of independent nation-states, although in the cases of French Indochina and the Dutch East Indies this was only accomplished after fierce armed struggles.

Southeast Asian nationalism cannot be seen as a mere imitation of its Western counterparts. When this did occur, as in the case of King Rama VI of Thailand (r. 1910–1925), who adopted the trappings of a modern Western state with little of its substance, the results were seldom lasting. Southeast Asian nationalists freely mined their own history and traditions in order to construct narratives in which their peoples would emerge from colonial control without abandoning their culture. Thus, the Trung sisters, who battled the Chinese domination of Vietnam (40–43 CE), could be portrayed as the embodiment of resistance to foreign conquerors. Sukarno (1901–1970), the first president of Indonesia (1945–1967), described his country as having a glorious past under the Srivijaya and Majapahit empires, as suffering under a Dutch Dark Age, and as being destined to soon emerge into a glorious independent future. Such independence would not be achieved by becoming Westerners but rather by studying the West, the reasons for its success, and even its own stories and methods of resistance and adapting them to local conditions (the American, French, and Russian revolutions inspired many).

Asian traditions were themselves not free of Western influences. It was Dutch historians and archaeologists who had “rediscovered” the Majapahit culture praised by Sukarno. French archaeologists excavated and restored the ruins of Angkor Wat and used it as a justification for colonial rule by downplaying the site's indigenous origins. It was later to be a key symbol for Cambodian nationalists of all stripes. In the 1920s, Western artists such as the painter Walter Spies studied Balinese art forms and popularized them for European consumption. The Balinese, in turn, adopted particular media—such as landscape painting—that they had never utilized before and made it a basis of a tourist industry that has thrived to the present day. Art, which in Ba-

lines society always had some degree of religious motivation, was tailored to a foreign clientele in order to allow for the preservation of many other aspects of traditional life.

■ Introduction: Imperialism

European empires in the late nineteenth and early twentieth centuries were often based on a sophisticated form of racism, epitomized by the phrase “white man’s burden.” The phrase originated from Rudyard Kipling’s 1899 poem that came to symbolize the notion of a European responsibility to take care of “half-devilish, half-childish races.” A sophisticated imperial racism was achieved through pseudoscientific underpinnings. Because empires, by definition, encompass multiethnic populations, crude and blunt forms of racism are actually counterproductive. The newly established pseudoscientific discipline of a natural history of humanity, or racial history as it was known at the time, explained the natural hierarchy of races, which justified the imperial enterprise and poisoned the social and cultural fabric of Europe for decades. According to racial history, cultures of the world are found in various stages of evolution, and this is a biological process, not a social process. The more “advanced” races are tasked with the need to take care of “childish” races.

Imperial structure reflected this hierarchy of races or nations. The British empire could serve as an excellent illustration because its system was the best developed. However, other imperial powers had similar systems. British imperial territories were divided into dominions, colonies, and protectorates. Dominions were the highest in the colonial hierarchy, particularly because they had the largest percentage of white Anglo-Saxon settlers; Canada, Australia, New Zealand, and Newfoundland were dominions, as

were the British possessions in the present-day United States before independence. Dominions had a substantial degree of internal autonomy, mainly because Anglo-Saxon “races” were considered mature enough for self-government. Representatives of self-governing dominions would gather occasionally for conferences in Britain, especially on the occasion of the coronation of the new monarch, who was at the same time the head of state of all British dominions.

Colonies, on the other hand, had a much lesser degree of autonomy and were actually divided into several categories. First, there were colonies that were ruled in consultation with an elected representative body, although usually with a fairly limited franchise. Second, there were colonies that were ruled in consultation with an appointed body or council. And third, there were colonies that were ruled directly by an appointed governor. The protectorates, another form of colonial status, were formally independent states that “voluntarily” surrendered some of their vital functions to the British empire. Usually this included financial, military, and foreign affairs, like in Egypt. While the British system of the racial hierarchy of rule was the best developed, other imperial powers followed similar procedures, such as the United States in Puerto Rico. In the French empire, some territories with a large French population would technically be part of France, but only the white French would be enfranchised and allowed to vote, such as in Algeria.

The colonies definitely proved their value to the metropolis during World War I and World

War II because they offered decisive military supplies and manpower, a crucial advantage over the blockaded Germany. Furthermore, during World War II Charles de Gaulle's Free France was organized primarily in the French colonial possessions. As the war progressed, more and more French colonies sided with de Gaulle and against the Nazi-controlled Vichy regime. Consequently, the French colonies managed to preserve for France its great power status.

Economic benefits of empire seemed obvious to many, but there were acrimonious debates about how profitable the colonies actually were. Some, especially in the French Third Republic, persistently argued that the empire cost too much. In the newly unified Germany (1871), Otto von Bismarck believed that colonies were a waste of money, and he was not alone in that opinion, even when in the beginning of the twentieth century Germany tried to increase its own empire. It is important to note that colonies brought both costs and benefits. The costs were most obvious when there were disturbances and rebellions. Sending a sizable army halfway across the world was never cheap. On the other hand, the benefits of colonies were most obvious to white people who served the empire in the colonies. Coming mostly from the lower middle class, during the course of their service in the colonies these individuals normally acquired considerable wealth and connections far beyond their social peers in the metropolis. Upon their return to England, France, Germany, Holland, or Belgium, these families would regularly climb up the social ladder.

Finally, the colonial experience had some positive consequences on the imperial capitals. Colonialism made a greater number of people aware of the diversity of world cultures. Comparative studies of all kinds became very popular, and new disciplines, such as musicology, ethnography, and anthropology, originated as intellectual reflections on the encounters between different world cultures. Crucial links developed between the progressive critics of imperialism in the metropolis and the colonial elites, who often sent their sons and daughters to study at imperial universities. It is important to note that the leaders of the anticolonial struggles, which in earnest started after World War II, had per-

sonal friends and political supporters among the progressives in the metropolis. There was also genuine—as well as superficial—interest in the arts of the colonial people, and this influenced many early-twentieth-century artistic movements, most importantly Cubism.

—*Alexander Mirkovic*

Japanese Imperialism

By the end of the nineteenth century, Japan had moved from a nation of relatively marginal influence to a dominant place in Asia. The most important focus of Japanese overseas activity in the 1870s and 1880s was the Korean peninsula. In 1876 Japan employed gunboat diplomacy to force the Treaty of Kanghwa on Korea, which opened three ports to trade with Japan and gave the Japanese extraterritorial jurisdiction within Korea. Japanese traders sharply expanded exports to Korea primarily by reselling European-manufactured goods first imported into Japan. Both the process and the end result were little different from the criticized techniques pursued by American commodore Matthew C. Perry in opening Japan to the West two decades earlier.

The Chinese imperial government also kept advisers in Korea to reform the Korean military and Korea's communications network. Meanwhile, Russian diplomats won increased influence at the Korean court, where some Koreans viewed them as offsetting the increasing Chinese and Japanese influence. With foreign powers pressing from all directions, Korea's own leaders desperately maneuvered to gain some breathing space and independence, although this proved impossible. In the early 1890s, long-simmering peasant anger at economic distress and the foreign presence erupted in a major uprising, the Tonghak Peasant Revolution (Tonghak Nongmin Undong). In 1894 this led directly to a war between China and Japan, fought in Korea. The ensuing Sino-Japanese War consisted primarily of naval engagements and ended in a complete Japanese victory by April 1895. In the peace treaty concluded at the Japanese port of Shimonoseki, Japan made clear its aspirations for an area of influence well beyond Korea. Japan won control of Taiwan, some nearby islands, the

Liaodong peninsula, and railroad building rights in southern Manchuria. The Southern Manchurian Railway later became the foundation of an expanding Japanese presence in Manchuria that lasted until the end of World War II.

Japanese leaders sought above all to solidify the nation's hegemony in Korea. By February 1904 the Japanese government had decided to secure its position in Korea—as well as Manchu-

ria—by force and declared war on Russia. This began the Russo-Japanese War, Japan's second major military struggle over Korea in a decade. This conflict was also the first time that a non-Western power defeated a major Western nation. Japan won a string of land battles as it advanced north on the Korean peninsula toward Manchuria. The Japanese Army also prevailed in January 1905 in a half-year siege of Port Arthur at the tip

THE SOUTH MANCHURIAN RAILWAY COMPANY

The South Manchurian Railway Company, also known by its initials SMR or Mantetsu in Japanese, was a multifaceted enterprise that blurred the line between blatant military imperialism and the cultural imperialism of the larger colonial project in Japanese Manchuria. Though the SMR was a separate operation from the Japanese Kwantung Army stationed in the region, its operations clearly benefited from the protection provided by the Japanese military. Established in 1906 after gaining the spoils of Russian railway lines in the aftermath of the Russo-Japanese War (1904–1905), the SMR encompassed far more than just trains and railway tracks up until its end in 1945. Calculated by overall capital and revenue garnered, the SMR constituted Japan's largest corporation. Company planners skillfully cultivated and distributed soybeans as the main cash crop in Manchuria so that by 1927 half of the world's supply came from the area. In addition to the lucrative freight and passenger lines operated by the SMR, the company ran iron and steel factories, machine workshops, flour milling operations, electric light companies, hospitals, schools, harbor facilities, hotels, and hot springs resorts. Moreover, the extensive research staff employed at the SMR comprised one of the largest think tanks of its time.

—Christopher Dewell

of the Liaodong peninsula. In May 1905 the Japanese Navy destroyed the Russian fleet off the coast of Korea.

However, the Japanese could not rout the Russian forces completely, and their own human and material losses were high. The Russians also desired to end the fighting, as they feared that a continued war abroad would incite revolutionary movements back home. In May 1905 the Japanese oligarchs secretly asked the American president, Theodore Roosevelt, to mediate. A treaty of peace was negotiated at Portsmouth, New Hampshire, and signed on September 5, 1905. The Japanese gained control of Russian railway lines in southern Manchuria and took over Russian leases in two Manchurian ports as well. They also won recognition of their exclusive rights to Korea. But aside from territorial rights on the southern half of the virtually unin-

habited Sakhalin Island, Japan emerged with no outright gains of land and no financial compensation. Public opinion at home indicated severe disappointment.

Nonetheless, Japan was now clearly in control of Korea. The Japanese Army, through the office of resident general, administered Korean foreign relations. The resident general increased his power in 1907 when Japan forced Gojong, the Gwangmu emperor (r. 1863–1907), to resign and disbanded the Korean Army. Three years later, Japan annexed Korea outright as a colony. Until 1945, the offices of the governor-general of Korea, appointed by the Japanese emperor, held complete military, judicial, legislative, and civil authority.

Back home in Japan, policies related to imperialism continued to shape domestic politics, in large part because such policies were expensive. Beginning in 1896, the government consistently sought new taxes to enforce Japan's foothold on the Asian mainland. Expansion of heavy industry, beginning around the turn of the century, was financed in part by the fruits of empire, such as the demand for arms production and the Sino-Japanese War indemnity, which subsidized steelmaking and shipbuilding.

Japan had now become a substantial colonial power. However, when the Meiji emperor died on July 29, 1912, the era of formal empire came to an end, giving way to the era of Taisho democracy. This democratic ferment took shape particularly during the 1920s but eventually became linked with nationalism, and the emphasis gradually shifted from democracy back to expansionism. During World War I, Japan seized German installations and investments in the Chinese province of Shantung, which included the leased territory of Kiaochow and a naval base at Tsingtao. Japan also occupied German island possessions in the western Pacific north of the Equator. Japanese occupation of the Pacific Islands (the Mariana, Palau, Caroline, and Marshall groups) continued after the Versailles treaties under the guise of a League of Nations mandate.

In September 1931 officers of Japan's Guangdong Army blew up a section of the South Manchuria Railway near Mukden (present-day Shenyang) that they were supposed to be guarding. They blamed the explosion on local Chinese

troops and then used the alleged guilt of the troops as a pretext for launching an attack upon them. This seizure of Manchuria (and its subsequent transformation to Manchukuo) marked a new stage in Japan's imperial development and conduct of international relations. Manchuria

was formally incorporated into the Japanese Empire, which signaled a reversion to the policy of formal expansion, a policy that was to culminate, once again, in war with China and then, disastrously, with America and the Allied Powers.

Belgian Imperialism

Despite its small size (11,600 square miles or 30,000 square kilometers), Belgium was a major imperial power from the 1880s to the 1960s, most notably in the central African nations of Congo (Zaire), Rwanda, and Burundi. Belgium in the late nineteenth century was a relatively new country. Originally ruled by the Netherlands, it had declared its independence in 1830, a move that received international backing at the Lon-

Leopold II, king of Belgium from 1865 until his death in 1909, is largely remembered for his expansion of Belgian power onto the African continent that came to be known as the Belgian Congo. (Library of Congress)

don Conference in 1831. The Dutch recognized Belgium's independence in 1839, the same year Belgium was declared a perpetually neutral country at a second London conference.

Motives for imperial expansion were numerous in the late nineteenth century. Among them were a belief in the racial superiority of the white man, a desire to civilize and Christianize allegedly inferior peoples, the need to find new markets and raw materials in the wake of the Industrial Revolution, and the desire to enhance a nation's prestige. In Belgium's case must be added the personality of King Leopold II (r. 1865–1909), who frequently complained that his small kingdom could not satiate his boundless ambitions and financial needs. Leopold successively considered acquiring colonies in Ethiopia, the Nile Delta, Argentina, Formosa (Taiwan), and Fiji before settling on the Congo. (His sister Charlotte also served as empress of Mexico from 1864 to 1867.)

The Congo was an ideal target for imperial takeover because it was divided into 250 distinct ethnic groups whose internecine wars had multiplied due to the international slave trade (sixteenth–nineteenth centuries). Most of the Congo remained terra incognita to Europeans until British explorers David Livingstone and Henry Morton Stanley (aka John Rowlands) explored the Congo basin in the 1860s and 1870s. Back in the Congo in 1879 as an agent of Leopold II, Stanley founded Léopoldville (now Kinshasa) near the mouth of the Congo River and then Stanleyville (now Kisangani) upriver. He also signed 450 treaties in which local chiefs surrendered much of their sovereignty to Leopold. Meanwhile, Leopold tried to portray himself as a humanitarian whose main goals were to Christianize the Congolese and to combat the slave trade through his International African Association (founded in 1876) and sponsorship of an antislavery conference in Brussels (1889).

The United States was the first to recognize Leopold's sovereignty in the Congo (1884). His claim was confirmed during the Berlin Conference (1884–1885) in which much of sub-Saharan Africa was apportioned between the various European powers. The colony, known as the Congo Free State, was run by a private company under the personal authority of Leopold himself, not under that of the Belgian state.

The Congo Free State (1885–1908) was one of the cruelest instances of European imperialism. Leopold's agents forcibly enrolled porters for the difficult trek around the rapids that lined the portion of the Congo River between Léopoldville and the Atlantic Ocean, then again resorted to forced labor when they needed workers to build a railroad along this route. Farther inland, the Congolese were obliged to deliver quotas of tropical products such as ivory and rubber. As late as 1906, the Congo Free State only had 1,500 European agents to administer a country 76 times as large as Belgium, so Leopold relied extensively on force and local allies to compel the Congolese to meet their quotas. He relied on native auxiliaries (or *capitas*) and created the Force Publique, an army officered by Europeans and manned by Congolese soldiers. The soldiers were known to hit recalcitrant workers with the *chicotte* (a whip made of hippopotamus hide), destroy villages when local leaders would not cooperate, jail relatives of workers sent to harvest rubber, and cut the hands of those who did not meet the quotas. It is estimated that the Congo's population dropped from 20 million to 10 million between 1885 and 1908, in part because of atrocities committed by Leopold's agents and in part because of a lower birth rate and famine caused by the requirement that healthy men focus solely on harvesting rubber.

Leopold's reputation as an antislavery activist was shattered in the 1890s when news about the atrocities started leaking out of the Congo. African American historian George Washington Williams wrote an *Open Letter* (1890) denouncing Leopold's rule. That same year, Joseph Conrad (aka, Józef Konrad Korzeniowski) briefly worked for the Congo Free State Company, an experience that formed the basis for his *Heart of Darkness* (1902). Another company employee was Englishman Edmund Morel, who was so horrified by the company's reliance on forced labor that he resigned and founded the *West African Mail* to publicize the atrocities. British consul Roger Casement, sent by the House of Commons to investigate the allegations, collaborated with Morel to create the Congo Reform Association. Mark Twain's *King Leopold's Soliloquy* (1905) and graphic photos of mutilated workers also helped spread popular outrage.

➤ MARK TWAIN ON KING LEOPOLD

Mark Twain was a vehement opponent of imperialism and often lent his pen and sharp wit to the anti-imperialist cause. He lashed out at the Congo Free State in his biting satire *King Leopold's Soliloquy* (1905), which provides a tongue-in-cheek defense of King Leopold's rule. The following is an excerpt:

"These meddlesome American missionaries! these frank British consuls! these blabbingblabbing Belgian-born traitor officials!—those tiresome parrots are always talking, always telling. They have told how for twenty years I have ruled the Congo State not as a trustee of the Powers, an agent, a subordinate, a foreman, but as a sovereign—sovereign over a fruitful domain four times as large as the German Empire—sovereign absolute, irresponsible, above all law; trampling the Berlin-made Congo charter under foot; barring out all foreign traders but myself; restricting commerce to myself, through concessionaires who are my creatures and confederates; seizing and holding the State as my personal property, the whole of its vast revenues as my private "swag"—mine, solely mine—claiming and holding its millions of people as my private property, my serfs, my slaves; their labor mine, with or without wage; the food they raise not their property but mine; the rubber, the ivory and all the other riches of the land mine—mine solely—and gathered for me by the men, the women and the little children under compulsion of lash and bullet, fire, starvation, mutilation and the halter."

Mark Twain, *King Leopold's Soliloquy: A Defense of His Congo Rule*. 2nd ed. Boston: P. R. Warren, 1905.

International criticism eventually prompted the Belgium government to purchase the company from Leopold in 1908. The colony, renamed Belgian Congo (1908–1960), was administered by a Belgian governor-general in Boma who took his orders from the colonial ministry in Brussels. During World War I (1914–1918), all but a small corner of neutral Belgium was invaded and occupied by Germany. Belgium allied itself with

France and England and invaded the German colony of German East Africa (present-day Tanzania) in 1916. Following Germany's defeat (1918), the Treaty of Versailles (1919) awarded Belgium some territories along the German border (Eupen and Malmédy) along with Ruanda-Urundi, a small colony carved out of German East Africa (present-day Rwanda and Burundi). Ruanda-Urundi was held as a League of Nations mandate and became a United Nations (UN) trust territory in 1946.

Cases of forced labor and racism persisted under the new colonial administration, but the overall pattern was one of misguided paternalism more than naked greed and violence. Belgian administrators alleged that the Congolese were not mature enough for self-rule and ought to be ruled by foreigners. Accordingly, whites continued to serve as military officers and top bureaucrats, racial segregation was the norm, and blacks were prohibited from purchasing liquor. Democratic institutions were nonexistent until communal councils were created three years before independence in 1957. As a counterpart, Belgium built facilities to benefit the Congolese, including a network of primary and vocational schools manned by Catholic, and more rarely Protestant, clergymen (higher education was almost nonexistent). Hospitals multiplied, leading to the eradication of sleeping sickness and a notable rise in life expectancy. Typical of the new Belgian mentality was Governor-General Pierre Ryckmans, who ruled the colony from 1934 to 1946 and summarized Belgium's mission in a 1932 book as "dominer pour servir" (to dominate in order to serve).

Belgium and its colonies sided with the United States in both World War II and the Cold War in which Congo's primary role was to supply strategic materials such as rubber and, increasingly, uranium. The colony's mineral riches made it one of the more prosperous in Africa, but the racism inherent in the colonial structure led to ever louder calls for independence by Congolese leaders such as Joseph Kasavubu and Patrice Lumumba. Following a series of demonstrations, the Belgian Congo obtained its independence in June 1960. It changed its name to Zaire under the rule of Mobutu Sese Seko (1965–1997) and is now known as the Democratic Re-

public of the Congo. Rwanda and Burundi obtained their independence in July 1962.

British Imperialism

During the years 1900–1945 the British empire reached its greatest geographical extent. It included self-governing white colonies known as dominions and a variety of territories with non-white populations called the dependent empire.

In recognition of the virtual independence of the dominions (for instance, Canada and New Zealand), the term "Empire" often was softened to become the British empire–Commonwealth and eventually the British commonwealth of Nations.

In the territories with nonwhite populations, the British ruled either autocratically, such as in Gibraltar and Hong Kong, or through traditional local rulers such as princes in parts of India, emirs in northern Nigeria, and sultans in Malaya. By far the most important part of the dependent empire was India over which a British viceroy ruled. India's army made Britain a great land power in the East. In 1900 Egypt nominally was part of the Ottoman Turkish Empire and later had its own king, but it was considered part of the British formal empire and was usually so noted on maps. A large informal empire of independent states whose economies Britain dominated also existed and included such areas as Argentina and southern China.

This half-century also was a period when the future appeared uncertain. The fate of the British empire was entwined with British status as a great power. Although Britain's empire was

► BRITISH EMPIRE TIMELINE, 1900–1945

- 1901—Federation of Australian colonies.
- 1902—End of Anglo–South African or Boer War.
- 1910—Federation of South African colonies.
- 1914—British empire, including self-governing (white or white-dominated) dominions, actively supported Britain in World War I.
- 1916—Easter Uprising in Ireland against British rule.
- 1917—Balfour Declaration called for a Jewish homeland in Palestine, then a Turkish province inhabited by Arabs.
- 1919—Peace treaties gave Britain formerly Turkish provinces and assigned Britain and several dominions German colonies as mandates (a kind of euphemism for colonies).
- 1919—British general ordered a massacre of unarmed Indians at Amritsar, an event that persuaded Indian nationalists to call for complete independence.
- 1919–1921—Irish nationalists fought guerrilla war against British government. The war ended with Irish partition, British acceptance of a self-governing Irish Free State, and home rule powers within the United Kingdom for Northern Ireland.
- 1920—Dominions separately represented in new League of Nations.
- 1926—A. J. Balfour definition of independent dominion status; Britain and the dominions thereafter often styled the Commonwealth in contrast with the British empire colonies that lacked self-government.
- 1931—Statute of Westminster; British Parliament renounced right to legislate for dominions.
- 1932—Ottawa Agreements, bilateral treaties that encouraged trade within the British empire–Commonwealth.
- 1935—Government of India Act offered Indians partial self-government.
- 1939—British empire and Commonwealth largely supported Britain in World War II, but Ireland remained neutral, and the major political movement in India, the Indian National Congress, refused to support Britain except at the price of complete self-government.
- 1941–1942—Japanese conquered Hong Kong, Malaya, Borneo, Burma, and, most importantly, Singapore, and invaded northeastern India and New Guinea.
- 1947—Partition of India created the independent states of India and Pakistan.

—David Fahey

a maritime empire defended by the Royal Navy, the British economy was the true foundation of British power. Relative to several other countries, British economic strength waned from the late nineteenth century onward, and pride in empire and a sense of crisis coexisted uneasily.

In 1900 Britain was at war with the Boers in South Africa. At the same time, the various Australian colonies united to form a federal state. After the British won the South African war, they quickly sought to reconcile the defeated Boers to a place in the empire. Britain united the Cape and Natal colonies and the former Boer republics, the Transvaal, and the Orange Free State in a confederation dominated by those Boers who were willing to cooperate with the British. This reconciliation of the white minorities came at the expense of the black majority. Organized by Mahatma Gandhi, the Indian minority in South Africa obtained minimal concessions from the

new white government. The status of the Indians as British subjects did them little good.

During World War I, the white dominions rallied to the side of Britain, although the French minority in Canada was unenthusiastic, and a few Boers in South Africa attempted a military rebellion. The heavy losses of Australian and New Zealand troops at Gallipoli brought about a new memorial day for their countries, Anzac Day, to honor members of the Australian and New Zealand Army Corps, or ANZAC. For its part, India supplied troops who played a major role in the campaign against Ottoman Turkey.

In the decades between the world wars the British empire was dominated by two stories: the codification of dominion status and the growth of Indian nationalism led by Gandhi. In practice, by the eve of World War I the dominions were independent states, although they seldom had their own ambassadors at foreign capitals. When the

League of Nations was formed, the dominions obtained representation there separate from that of the United Kingdom. In 1926 under the leadership of A. J. Balfour, dominion status was vaguely defined as “autonomous communities within the British empire, equal in status, in no way subordinate one to another in any aspect of their domestic or external affairs, though united by a common allegiance to the Crown and freely associated as members of the British commonwealth of Nations.” In 1931 Parliament renounced any right to legislate for the dominions in the Statute of Westminster. In India, events such as the Amritsar Massacre and Gandhi’s nonviolent mobilization of the masses turned the Indian National Congress into a popular movement for independence. The British vainly offered concessions, especially in the Government of India Act of 1935 that gave Indians a dominant position in provincial government and a substantial say in the central government. As a result of fears about Hindu domination and personal ambitions, the Muslim League demanded recognition as the representatives of the entire Muslim minority and began to speak about an Islamic state.

There were other important interwar stories: the Balfour Declaration calling for a Jewish national home in Palestine, insurrection, partition, and dominion status for the Irish Free State, and the development of would-be white settler dominions in Kenya and southern Rhodesia. Moreover, in 1932 Britain attempted in the Ottawa agreements to establish economic unity with the dominions through a system of tariffs combined with imperial preference.

During World War II the dominions and the dependent empire for the most part again rallied to the support of Britain, but the Irish Free State remained neutral, and the Indian National Congress refused its support so long as Britain denied India immediate independence. In addition, a few Indians who were prisoners of war of the Japanese joined a revolutionary Indian army that fought as allies of the Japanese against the British. In contrast, a huge Indian army served Britain. The fall of the great naval fortress of Singapore undermined British prestige in the East. As a practical matter, Australia turned to the United States as its main ally in the Pacific war. Britain was fighting for its life against Germany in Europe. Al-

though Britain lacked the resources to defend all of its empire, the empire contributed mightily to the war effort. For instance, West African troops fought for Britain in distant Burma.

After the war concluded, the British empire quickly came to an end in South Asia. What had been India was partitioned between a Hindu-majority but officially secular India and the Islamic state of Pakistan (later divided between Bangladesh in the east and what remained of Pakistan in the west). Ceylon (Sri Lanka), like India and Pakistan, remained in the Commonwealth after securing independence. Burma became a republic outside the Commonwealth, as did Israel in the Middle East. The Irish Republic also withdrew from the Commonwealth. Vast parts of the old informal empire such as, for instance, the cities of Shanghai and Canton and the rest of southern China after the Chinese communists established the People’s Republic of China, were lost too.

Britain emerged from World War II as an exhausted victor, only nominally the equal of its more powerful allies, the United States and the Soviet Union, but still regarded itself as a great power. Few people in Britain expected that its empire in Africa and in the Caribbean would come to a rapid end. In 1950 despite the loss of India, the end of the British empire seemed distant, beyond the lifetime of the youngest British child.

French Imperialism

At its peak in the first half of the twentieth century, the French colonial empire was second only to Great Britain’s and stretched from Africa to the Middle East, Southeast Asia, the Pacific, and the Caribbean. Even though the empire grew quite popular after World War I (1914–1918) and

influenced the realms of art and popular culture, the French military difficulties during World War II (1939–1945) set the stage for a movement of decolonization in the decades that followed.

The French Third Republic (1870–1940) drastically expanded the size of France's empire, creating what is known as the Second Empire. Contrary to its prerevolutionary predecessor, this empire was centered in Africa and Indochina, not India and North America. Motives for building the empire were varied: belief in the scientific racism inspired by Charles Darwin, the aspiration to spread French civilization (*mission civilisatrice*), the need for markets and raw materials in the wake of the Industrial Revolution, and the desire to offset France's defeat during the Franco-Prussian War (1870–1871). France faced no overpopulation crisis, and immigration rates to the empire remained low outside of Algeria.

France expanded in Southeast Asia at the behest of Jules Ferry (premier during 1880–1881 and 1883–1885). France took Tonkin and Annam (Central and North Vietnam, 1883), then Laos (1893); these, in addition to Cochinchina and Cambodia, were integrated into French Indochina (1887). The International Conference of Berlin (1884–1885) granted France large tracts of Africa. French presence in or even geographical knowledge about the African interior was almost nil at the time, but in the following decade France succeeded in enforcing its territorial claims. In West Africa, France gained Côte d'Ivoire (Ivory Coast), Dahomey (Benin), Guinea, Mali, Mauritania, Niger, and Upper Volta (Burkina Faso) in addition to Sénégal. These formed the Afrique Occidentale Française (French West Africa, AOF) in 1895. In Central Africa, France obtained Chad, the French Congo (Congo-Brazzaville), Gabon, and Ubangi-Shari (Central African Republic). These formed the Afrique Equatoriale Française (French Equatorial Africa, AEF) in 1910. France also obtained Madagascar and Djibouti. France hoped that a French-dominated Sudan would link Djibouti to the AEF and AOF but abandoned this project after the Fashoda incident with Great Britain (1898).

In the Arab world, France established a protectorate in Tunisia (1881) and Morocco (1911), the latter following a conference in Algieras (1906) and a series of crises with Germany

(1905, 1908, 1911). The Ottoman Empire's breakup after World War I added Syria and Lebanon to an already considerable empire. Germany's defeat in the same war also gave France parts of Togo and Cameroon. During the interwar years, the empire peaked at 4.767 million square miles (12.347 million square kilometers), not including metropolitan France.

The colonies were ruled according to a variety of statuses based on the alleged maturity of the local races, on the size of the European population, and on how long the territory had been in French hands. Colonies proper (such as most of sub-Saharan Africa) were administered by a white administrative hierarchy selected in Paris. In protectorates (such as Morocco), local rulers remained in place; they continued to administer internal affairs but had to defer to French consuls for matters such as foreign policy and defense. Syria and Lebanon were held as League of Nations mandates and were thus nominally entrusted to France temporarily before these countries could achieve full independence. In 1848 parts of Algeria were turned into *départements* (a French administrative unit) and were thus legally considered an integral part of France. Martinique, Guadeloupe, Réunion, and Guyana gained this status in 1946.

Inhabitants of the colonies were also separated between full-fledged citizens of France (with full voting and legal rights) and mere subjects of the empire. In Algeria religion was the main dividing line, as settlers of European descent, Jews, and a few secular Muslims were allowed to vote in national elections, while the vast majority of Muslims were disenfranchised and subjected to Muslim law. In West Africa, black inhabitants were allowed to elect deputies to the French national assembly only when, as in Sénégal's Saint-Louis and Gorée, they had been assimilated after lengthy membership in the empire.

Prior to World War I, France used its empire primarily to obtain raw materials such as nickel (New Caledonia), rubber (French Congo and Indochina), cocoa (Ivory Coast), and sugar (Guadeloupe and Martinique). The overall profitability of the empire remains in dispute, for France financed infrastructure and health projects as part of its civilizing mission. The French public

remained ambivalent as nationalists such as Paul Déroulède complained that imperial expansion was a ploy to divert the public attentions away from the recovery of Alsace and Lorraine.

During World War I, access to raw materials, overseas ports, and colonial conscripts gave France and Great Britain a noticeable edge over colonies-deprived Germany. France thus enlarged its empire at the expense of Germany and the Ottoman Empire and organized a colonial exhibition (1931) whose popularity with the French public matched that of the empire. The empire also had a notable artistic influence, as avant-garde artists present in France, such as Pablo Picasso and the cubists, expressed their admiration for the naive or primitive style of sub-Saharan African statues. The empire's strategic value was proven again following France's surrender to Germany in 1940. Most and eventually all of France was occupied or annexed by Germany, but Philippe Pétain's Vichy France kept control of the navy and the empire. Vichy France and Charles de Gaulle's rival Free French subsequently competed for the loyalty of the colonies. The African colonies also provided troops and a starting point for Philippe Leclerc de Hautecloque's campaign against Nazi Germany.

Ironically, the colonies' key wartime role also marked the beginning of the decolonization movement. In Brazzaville (French Congo), de Gaulle promised eventual emancipation to incite colonies to contribute to the war effort (1944). In Indochina, the Japanese occupation made it difficult for France to reassert its authority after the war and led to a war for independence (1945–1954).

German Imperialism

Compared to Britain, France, Spain, Portugal, and the Netherlands, Germany acquired its overseas colonies quite late and held onto them for a much shorter time. After 1900 Germany attempted to fundamentally alter the culture and economy of the regions it conquered in an effort to make them attractive to German settlers or investment. The government, however, was faced with large-scale colonial rebellions as a result of its policies and actions. In fact, uprisings in two of the German-held colonies from 1904 to 1907 were the largest anticolonial rebellions in sub-Saharan Africa up to that time. In response, all major and minor insurgencies were ruthlessly suppressed by German arms. In the wake of these revolts and other colonial scandals, German leaders sought to reform their colonial system but with limited success.

German colonies covered more than 656,373 square miles (1.7 million square kilometers) with a population of around 13 million inhabitants. In comparison, this was about three times the size of Germany in 1914 (approximately 208,495 square miles, 540,000 square kilometers), which had a population of about 68 million people. The German Reich's largest and most important colonies were in Africa: Togo, Cameroon, South-West Africa (present-day Namibia), and German East Africa (present-day Tanzania). The remainder of Germany's empire encompassed the Pacific archipelagos (the Bismarcks, the Marshalls, the Carolines, the Marianas), northeastern New Guinea, part of Samoa, and Kiaochow in China.

South-West Africa supplied cattle, copper, and diamonds for Germany; German East Africa produced coffee and cotton; Togo and Cameroon exported palm oil, cacao, cotton, rubber, and coconuts; and Samoa cultivated copra, the dried meat of the coconut. Compared to the colonial possessions of Britain and France, Germany's colonies were small and nonlucrative.

The failure of private chartered firms such as the German East Africa Company to govern and exploit the German protectorates effectively caused the German government to assume direct administrative control of the colonies in the late 1890s, install governors, and establish mili-

tary and civil service structures. Administration of the colonies had thus become an economic burden on the German state and was greatly politicized. Despite the wide variations in indigenous economic development, resources, and political organization that the colonies possessed, German authorities faced the same dilemma everywhere: how to make a colony profitable and therefore attractive to German settlers, traders, and investors. The key to attracting capital and settlers (usually German) lay in solving problems of land, labor, and sovereignty in the colonies. Such attempts, however, brought colonial administrators into direct contact and often conflict with indigenous peoples.

Given budgetary constraints, the colonial administration's preference was to govern indirectly using established indigenous political structures if paramount chiefs and headmen acknowledged German suzerainty. This was the cheapest and most efficient way to maintain peace, but German authorities would also play indigenous political units against each other and preserve tensions between them so that the German state was the final arbiter of internal politics. However, settlers became an economic element in some colonies that could not be accommodated by a native policy that validated indigenous political structures and economic rights.

The two colonies that had large-scale rebellions, South-West Africa and German East Africa, were the ones with the most German settlers, and both colonies had undergone the most drastic economic and political transformations. According to official estimates, in 1912 South-West Africa had 14,816 white inhabitants, German East Africa had 4,886, Cameroon had 1,537, and Togo had 345. Some settlers purchased land from the natives, while others simply occupied land or had it granted to them by the colonial government. In South-West Africa, most settlers engaged in cattle ranching, which directly competed with native people's livelihood and often displaced their herds, causing great tension. In German East Africa, Europeans took land for rubber and cotton plantations, again displacing some of the local clans. In all colonies, labor was needed to work the ranches, farms, and plantations that the Europeans had established, and finding sufficient labor was seldom easy. In general, the colonial adminis-

tration resorted to taxes to compel Africans and Pacific Islanders to work outside the traditional economic sectors. One option was that the locals had to take jobs that paid wages so they could pay taxes, such as the hut tax, in cash. The other option was to perform a *corvée*, which was a tax paid by direct labor on roads, installation, and farms. Native peoples resented both forms of coerced participation in the colonial economy and the state that enforced them. These policies wrecked the indigenous economy, as men and women neglected their own animals and fields to labor elsewhere. Resentment against forced labor sparked the 1905 Maji Maji Revolt in German East Africa, and anger toward a system of wage labor, indebtedness, and tribal reserves in South-West Africa led to the Herero and Nama wars of 1904–1907. The revolts were directed at ending German power and reasserting indigenous political and economic systems. In response to these uprisings, the Germans conducted genocidal warfare. They destroyed all indigenous economic and political structures in the rebellious areas, thereby creating a landless African proletariat from the survivors whose only source of income would be their labor in European-controlled enterprises.

In Togo, Cameroon, and Samoa, native structures had already adapted to commercial capitalism and international markets, and native life was far less disrupted by colonialism. Togo was considered Germany's model colony because it provided trade surpluses and methods of governance that integrated Africans into the colonial economy in ways that enhanced colonial and peasant profitability. The Germans brought scientific cultivation to Togo's main export crops and developed its transportation infrastructure to the highest level in Africa. Even these colonies, however, were arenas for forcible exploitation in which the European position was maintained through violence or the threat of violence.

The German government's resort to violence to regulate affairs with indigenous peoples caused a major crisis in German politics in 1906. The violent campaigns against the Hereros, Namas, and peoples of southern German East Africa as well as the constant reports of ill treatment of indigenes in virtually every German colony since 1895 caused the German Reichstag (parliament) to reject a bill in December 1906 to allocate

additional funds to finance military operations in South-West Africa. After new elections in 1907 vindicated the government's policy, the chancellor, Bernhard von Bülow (1849–1929), appointed Bernhard Dernburg (1865–1937) to head the Colonial Office and initiate reforms to make the colonies profitable by developing their resources scientifically and by treating the native peoples with greater respect. His reforms included the founding of specialized agricultural research stations to promote the cultivation of particular products such as cotton and tobacco, the abolition of forced labor (except on public works), and the reduction in the use of corporal punishment on indigenes. Even so, the labor regulations were hard to enforce in the colonies since planters and farmers were opposed to them.

Germany's colonial possessions were becoming more valuable to the nation as a result of greater investment and exploitation after 1907. Total colonial trade quadrupled from 60 million marks in 1902 to 260 million marks in 1912;

however, the proportion of colonial trade to total German trade grew to only 1.2 percent.

Germany lost its overseas colonies during the course of World War I when Allied troops conquered the Pacific islands (August 1914), Togo (August 1914), South-West Africa (July 1915), Cameroon (February 1916), and German East Africa (November 1917). The loss of the German imperial possessions was ratified by the Treaty of Versailles in 1919.

■ Introduction: Nationalism in Shaping Society and Culture

The idea of the nation-state—a well defined geographical area populated by people who believe they are bound together through commonalities in background, language, and culture—became important in the nineteenth century, and was the dominant political identity by 1900. Many colonial territories and cultural enclaves actively agitated for self-determination. The drive toward nationalism was encouraged when U.S. president Woodrow Wilson included “national self-determination” as one of the Fourteen Points he proposed in a speech before a joint session of the U.S. Congress that, in part, outlined his vision for the postwar world. Wilson's Fourteen Points were widely distributed and encouraged many that Wilson's principles would inform the basis of a treaty after Germany's surrender ended World War I. Although little of Wilson's idealism survived the diplomatic process, as representatives met to forge the Treaty of Versailles, the hope for national sovereignty increased across much

of the world. The treaty resulted in the establishment of new sovereign states and mandates (quasi-colonial holdings) established from the former Ottoman, Austro-Hungarian, and Russian empires, and encouraged nationalistic hopes across the globe, notably in Southeast Asia, the Middle East, and Africa. The ambition to create ethnically, linguistically, and culturally homogeneous states had a significant impact on political and social developments, shaping national institutions, cultural activity, and traditions, as well as triggering new conflicts.

and Carolyn Neel

Pan-Africanism

Pan-Africanism, an intellectual and social movement, developed simultaneously inside and outside of Africa toward the end of the nineteenth century as a reaction to slavery and the impact of

► GEORGE PADMORE

George Padmore (ca. 1902–1959), a potent intellectual with fiery dedication to socialism, Pan-Africanism, and African nationalism, counseled many young Africans who led their countries to independence. Born Malcolm Ian Meredith Nurse, he transformed himself between 1927 and 1933 into George Padmore, powerful member of the Profintern or Red International of Labor Unions (RILU) and an international revolutionary. He wrote *Life and Struggles of Negro Toilers* and edited the monthly journal *The Negro Worker*. From 1935 until 1957 Padmore developed his Pan-African ideology and published extensively, including *Pan-Africanism or Communism: The Coming Struggle for Africa* (1956). He mentored Kwame Nkrumah (Ghana), educating him in Marxist philosophy and economic theory. In 1956 Padmore attended Ghana's independence celebrations and became Ghana's adviser for African affairs.

—Lorna Lueker Zukas

European colonialism on Africa. Pan-Africanism was theorized as an African pride movement that stipulated that black people everywhere should be proud of Africa's history and heritage and struggle against racism, colonialism, and white oppression. Pan-Africanism developed as an inclusive ideology linking peoples of African descent around the world to the continent of Africa. For African and African American intellectuals and activists, Pan-Africanism was a call for nationalism and self-determination. Pan-African ideologies united the struggles against colonialism in Africa and against racial hierarchies in the Americas. An underlying principle was that African self-determination was necessary for the true development of Africa and for the development of humankind.

Early Pan-African theories can be traced to the work of William Edward Burghardt (W. E. B.) Du Bois (1868–1963), Edward Wilmot Blyden (1832–1912), Alexander Crummell (1819–1898), Martin R. Delany (1812–1885), and Marcus Garvey (1887–1940). Henry Sylvester Williams (1869–1911), a London barrister born in Trinidad, organized the first Pan-Africanist conference in 1900 in an effort to develop a working plan for a program of African self-determination.

In Africa, both James Africanus Beal Horton (1835–1883) and James “Holy” Johnson (1836–1917) were early Pan-Africanist and supporters of African nationalism. Both men were European-educated Christian Africans who were committed to development, Christianity, and Africa. They mistrusted imperial powers and

believed that the only way to rid Africa of imperialist rule was to create autonomous African nation-states with black majority rule. They helped form African churches and associations as a means to cultural nationalism and economic self-determination. The goal was to provide blacks in Africa and the diaspora dignity and an end to oppression.

Never a coherent doctrine, Pan-Africanism in the first half of the twentieth century was shaped by the work of two very different men, Marcus Garvey and W. E. B. Du Bois. Despite working toward the common goals of dignity and self-determination for black people worldwide, these men were dissimilar in style and approach to the implementation of Pan-Africanism. Garvey, born in Jamaica, moved to New York in 1916 and founded the Universal Negro Improvement Association (UNIA). His talk of black pride resonated with the African American population in New York and abroad. In 1920 he organized an international convention known as the First Black Parliament, with delegates from 25 nations meeting in New York City. As part of this convention Garvey arranged a march in Harlem in which 50,000 people reportedly participated. Garvey promoted the ideas of Africans moving back to Africa in order to create an “Africa for Africans.” He believed that the key to ending discrimination and oppression was the development of black self-pride, black nationalism, and black economic self-determination. Garvey owned numerous business ventures including Black Star Lines, an international commercial and passenger steamship line. His other business concerns included the African Commercial League/African Factories Corporation, which ran small businesses in Harlem; the Liberian Construction Loan, a fund-raising scheme to promote development of Liberia; and Liberty University, a vocational training school. In the 1920s, Garveyism was the most popular form of Pan-Africanism among diasporic blacks in Europe, the United States, and the West Indies as well as within Africa.

W. E. B. Du Bois was, in many ways, Garvey’s opposite. Du Bois was an intellectual whose activism was grounded in meticulous scholarship about the social and cultural circumstances of black Americans. He was cofounder of the Na-

tional Association for the Advancement of Colored People (NAACP) and served as editor for *The Crisis*, the NAACP newsletter, from 1910 to 1934. Du Bois formulated a global perspective to the problems of black Americans and Africans. To this end, he organized a series of Pan-African Congresses that spanned three decades. In Paris, the 1919 congress coincided with the Versailles Peace Conference at the end of World War I. Du Bois attempted to persuade world leaders that the self-determination fought for by Europe in the war should be applied to Africans as well as Europeans. The Second Pan-African Congress in 1921 developed the *Declaration to the World* or *The London Manifesto*. The manifesto noted the failure of the British empire to educate Africans, promote self-sufficiency, or enable Africans to govern themselves. In 1923 and 1927 the successive congresses adopted resolutions calling for the development of Africa for Africans, majority rule in the colonies, the end of white hegemony in Africa, and, finally, an end to lynching and mob rule in the United States.

These congresses provided few political gains, and within a few years, under the influence of Harlem Renaissance writers and artists such as Zora Neal Hurston, Langston Hughes, Claude McKay, and Paul Robeson, Pan-Africanists in the Americas focused their attention on cultural issues. They looked to precolonial Africa for new sensibilities, a proud heritage, and an unshackled sense of self.

In Europe and Africa, other Pan-Africanist organizations arose. Perhaps the most important of these was the negritude movement, identified with nationalists and intellectuals from France’s Caribbean and African colonies. Léopold Senghor and Aimé Césaire founded the movement in Paris in 1933. The fundamental idea behind this movement was that people of African heritage everywhere possessed an African personality. The movement supported the cause of African nationalism, particularly within the French colonial context.

It was the Fifth Pan-African Congress, held in Manchester, England, in 1945, that ushered in the era of revolutionary change that would follow. The most radical of the congresses, it was attended by numerous African activists including Peter Abrahams for the African National

Congress, and a number of future African political leaders served as delegates: Hastings Banda of Malawi, Kwame Nkrumah of Ghana, Obafemi Awolowo of Nigeria, and Jomo Kenyatta of Kenya. Du Bois and Trinidadian radical George Padmore, the Pan-Africanist leader who encouraged black nationalism in Africa and who was Nkrumah's mentor, were also present. The 1945 congress opened the door for workers to have a voice in the Pan-African movement. The attendees had a clear mission to end colonial rule and racial discrimination in Africa. They were determined to carry forth a global human rights agenda, overcome imperialism, and press for economic opportunities and equality for workers around the world.

Arab Nationalism

Arab nationalism, a social and political movement that sought to unite the Arabs on the basis of a common language and history, underwent broad changes between the start of the twentieth century and World War II. The foundations of Arab nationalism are largely found within the Islamic revivalist movement of the late Ottoman period during which Arabism was predominantly a cultural movement seeking to strengthen the Ottoman state against the encroachments of the European powers and local administrative autonomy within the Ottoman Empire. By the 1940s Arab nationalism would take on numerous strands, generally from either the liberal Hashemite-led extreme to the radical Pan-Arab unionist extreme led by activists such as Michel Aflaq and Salah al-Din al-Bitar and their Baath Party.

The period directly preceding the advent of Arab nationalism was an era of tremendous institutional change within the Ottoman Empire. The loss of large tracts of Ottoman territory and an overall weakness in comparison to the European powers led to a series of Western-influenced ad-

ministrative and educational reforms called the Tanzimat period. The roots of proto-nationalist Arabism, a cultural movement that did not conflict with the state ideology of Ottomanism, came into existence during this period. Early research on the subject of Arab nationalism has tended to emphasize the importance of the Arab literary *nahda*, or renaissance, centered around the missionary schools of Beirut. The importance of this activity cannot be totally refuted, especially in regard to the modernization of the Arabic language. Recent scholarship, however, has effectively shown that the movement that would become Arab nationalism was largely a product of late-nineteenth-century Islamic revivalism.

Arabism largely grew out of the Ottoman Empire's inability to keep up with the developments in the Western states and developed out of the attempts to modernize the Ottoman state through an Islamic framework. Islamic revivalism was premised on the doctrine of Salafi Islam, the notion that true Islam is based upon the religious and social beliefs advocated by the first generation of Muslims. A central figure in this movement was the Egyptian scholar Mohammed Abduh. Abduh's protégé, Abd al-Rahman al-Kawakibi, continued in this tradition during the first decade of the twentieth century. Al-Kawakibi proscribed that it was necessary for the Ottoman Empire to have an Arab caliph, separate from the Turkish Ottoman sultan, presiding over the religious affairs of the empire.

In 1908 the Young Turk Revolution, led by the İttihad ve Terakki Cemiyeti (Committee of Union and Progress, CUP), ushered in the second constitutional period of the Ottoman Empire along with a renewed focus on Ottomanism. Under the leadership of the CUP, a great emphasis was placed on the need for a strong central power within the empire and a move away from traditional Ottoman administrative autonomy for the various religious and ethnic groups. The standardization of the use of the Turkish language within all Ottoman administrative offices, secondary schools, and courts and the increase in the amount of Turks holding high state offices led to allegations that centralization was more akin to Turkification. The lack of CUP action toward curtailing Zionist settlement in Palestine, the 1911 Italian occupation of Libya, and the

concession to the British Lynch Company on the Tigris and Euphrates rivers led the Arab political class to shift toward anticentralization. In response to the CUP administrative measures, various Arabist organizations and societies started to sprout. The two most prominent of these secret societies were the civilian-led al-Fatat (Young Arab Society) and the Ottoman military officer-led al-Ahd (Covenant).

Of particular interest to the study of Arab nationalism's development would be the connections that these two secret societies would have with the Hashemite family in the al-Hejaz (Hijaz, Hedjaz). The Hashemite family was led by Sharif Hussein, the emir of Mecca, whose sons Feisal and Abdullah would become key intermediaries between their father and the Arab nationalists in Syria. During the early phase of World War I, Hussein had committed the al-Hejaz-based forces under his command to assist the Ottoman effort. Correspondence was later initiated in 1915 between Hussein and the British high commissioner at Cairo, Sir Henry McMahon, through which it was agreed that the emir of Mecca would align with the British and revolt against the Ottoman Empire in exchange for promises of postwar Arab independence with a Hashemite-ruled monarchy. Consequently, in 1916 the Arab Revolt was initiated against the Ottoman Empire, the result of which would be the empire's loss of all its remaining territories and the occupation of these territories by British-, French-, and Hashemite-led forces. It should be noted that Arab nationalism was a minority movement before World War I, and until the Arab Revolt the regions where Arab nationalism was strongest, such as Syria and Iraq, never revolted against the Ottoman Empire. Nevertheless, the Arab Revolt did more to advance Arab nationalism than any other factor, as it made Ottomanism an unworkable ideology after the empire's defeat in the war.

Along with the end of Ottoman rule over the Arab territories and the rise of Arab nationalism to ideological supremacy during the period between the two world wars, there was also an increased consideration given to defining secular theories of Arabism. The chief theorist of Arab nationalism, Sati al-Husri, put forward the notion that language and history were the critical bonds that held together a nation. The Syrian academic

Qustantin Zurayq wrote on the necessity of achieving an Arab national consciousness, while during the 1930s and into the 1940s the French-educated Syrian teachers Michel Aflaq and Salah al-Din al-Bitar began to foster among their students the foundations of what would become the Arab Baath Party. The Baath Party was a Pan-Arab nationalist movement that professed socialism, anti-imperialism, and the belief in the Arab mission. In addition, French and British imperialism were major factors in the strengthening of the Pan-Arabist movement.

During the first years of the post-Ottoman period, the political leadership of Arab nationalists rested in the hands of the Hashemites. They believed that through the McMahon-Hussein correspondence Britain had promised their family the kingship over the Arabs. However, due to the secret 1916 Sykes-Picot Agreement between the French and the British, the Arab countries were mostly divided into regions of French and British influence. An exception to this process was the al-Hejaz, which was conquered by Ibn Saud and annexed into his kingdom in 1924. Feisal was the monarch of a short-lived (1918–1920) Arab state based in Syria, but his state was eventually conquered by the French. In 1921 British authorities appointed Abdullah as the emir of Transjordan, while his brother, Feisal, became king of Iraq. Both Abdullah and Feisal reigned under the indirect rule of the British. These appointments did not curb Hashemite ambitions, and the brothers ultimately sought to expand their rule by promoting their respective Arab confederation proposals. The creation of the Arab League in 1945 was the only tangible realization of Pan-Arabism during this period. With British assistance, the Arab League was created for the coordination of affairs between the Arab states and its seven founding members: Egypt, Saudi Arabia, Syria, Lebanon, Iraq, Transjordan, and Yemen.

Indian Nationalism

Indian nationalism can broadly be defined as the ethnically, politically, socially, and economically derived desire for the creation of an independent Indian nation-state. Indian nationalism has been difficult to define because the country and the nationalist desires within the subcontinent are physically and metaphorically vast, encompassing the great variety evident in language, cultural tradition, historical experience, and economic hierarchy.

Although the first examples of modern nationalist sentiment came from European and neo-European locales such as North America, the rhetoric of nationalism quickly spread to all corners of the world. Modern nationalism defines the term “nation” as a unified community bound together by one overarching political structure. This Enlightenment-era philosophy entered India via the imperial enterprise in the manner of imperial control and the structure and concepts offered by imperial education. Paradoxically, nationalist movements derived inspiration and motivation from historical identifiers, typically predating European expansion and imperialism and other modern developments. The nation, as the unit of analysis in a premodern sense, is defined less by unity in governance and more by symbols and traditions, which anthropologists refer to as “primordial.” Primordial national identity is based on culture, ethnicity, religion, and linguistics. Nationalism on the subcontinent of India, in the era of European imperialism, developed and evolved through the incorporation of various facets of both modern and primordial nationalist traditions, resulting in the heterogeneous national makeup of the region. Although Indian nationalism appeared prior to the first meeting of the Indian National Congress (INC) in 1885, it was the INC that represented the first viable group organized with a modern national-

➤ RASHTRIYA SWAYAMSEVAK SANGH

The Rashtriya Swayamsevak Sangh (National Volunteers' Union (RSS) was founded by Keshava Baliram Hedgewar (1889–1940) in 1925. As an organization, the RSS advocated a culturally defined nationalism built on the regeneration of Hindu traditions and principles. Early RSS tenants focused on overtly anti-Muslim and anti-Christian messages. Before independence, the RSS purposefully followed an apolitical path, focusing instead on cultural and social transformation guided by Hindu values. A strong component of the social preservation advocated by the RSS was an emphasis on physical strength and military grandeur. As a consequence, RSS rhetoric encouraged comparisons between this form of Hindu nationalism and its contemporary European fascism. The later Bharatiya Janata Party, a right-wing Hindu political party, integrated much of the RSS agenda into its political platform, including the anti-Muslim and anti-Christian rhetoric.

—Marianne A. Rhett

ist ethos. This form of nineteenth-century Indian nationalism called for unity among the general populace of the subcontinent. It was clear that subjects of the subcontinent spoke universally about wanting an independent self-regulated state. What form this state should take, however, created rifts within the region. Divisions manifested in debates about Great Britain's role in the transition of the subcontinent to an independent Indian state.

As the nineteenth century waned, not only did questions of British involvement cause disunity in the nationalist cause, but definitions of what was “Indian” also fractured the larger movement. As primordial nationalist rhetoric took a greater role in motivating the populace, who was to be included as Indian was questioned in particular, but certainly not solely, by religiously centered Hindu and Islamic nationalists who advocated a redefinition of the Indian nation. While the bulk of Indian nationalism continued to be channeled through the auspices of the INC, minority groups and disenfranchised factions, who believed that the INC did not speak directly for their own causes, took up a

Sir Muhammad Iqbal, the poet-philosopher, was an early advocate of an independent Muslim state on the Indian subcontinent. (Pakistan Mission to the United Nations)

more pointed and typically more primordial national rhetoric.

Muhammad Ali Jinnah, an early advocate of the unity between Muslims and Hindus who later became the future governor-general of Pakistan, had by the 1920s split with the INC and began to advocate a platform seeking to safeguard Muslim rights in an independent India. By 1919 portions of the Indo-Muslim population became involved in the Khalifat movement, which was desirous of casting out British imperial rule but was also distinctly Islamic, even Pan-Islamic in message and procedure. The Khalifat movement in essence focused on strengthening the political position of the minority Islamic community in the subcontinent, also uniting that same community with the global Islamic community, the *umma*. Attentive to the future of the spiritual leadership of the *umma* and the role of the Islamic caliph, then seated in Istanbul, Khalifatists developed their political agendas at the Aligarh University in Uttar Pradesh.

Sir Muhammad Iqbal (1877–1938), Indian poet, philosopher, and politician, began his political career much as Jinnah had with a view toward Indian independence. Gradually, however, his ambition changed as he began to argue for an Indo-Islamic nationalism that sought to protect the rights of India's Islamic minority. He maintained that nationality was not determined by language or geographic location but rather by people advocating the same spiritual worldview. Iqbal believed that Islam offered alternative models to European concepts, in particular nationalism. Membership in a given nation was, according to Iqbal, dependent upon the uniting precepts of the community, in this case religion.

Not long after Indo-Islamic nationalism appeared, Indo-Hindu nationalism found its footing too. In his 1923 pamphlet *Hindutva: Who Is Hindu?* V. D. Savarkar contended that Hindus constitute a nation by virtue of their blood relation, common heritage, and tradition. Much like Islamic nationalism elsewhere in India, *Hindutva* (*Hinduness*) focused on a culturally derived Hindu-centric concept for an Indian nation-state. In political activity *Hindutva* found its voice through the Rashtriya Swayamsevak Sangh (RSS), founded in 1925. Savarkar's work called upon Hindus to take up the mantle of cultural custodians for India's identity. Despite the efforts of the INC to unify the Indian populace under the guise of decolonization and governmental cohesion, the RSS promoted a nationalist rhetoric that highlighted the tensions between the Hindu and Islamic communities.

Although a general sense of Indian nationalism, particularly one centered on ending imperial rule, continued to be the sustaining force across the subcontinent, under the guidance of Mahatma Gandhi and the INC in the 1930s and 1940s, the reality of a nation's definition within India was far more complex. The fracturing of nationalist rhetoric marked by primordially defined differences created rifts across the subcontinent. In 1947 India and Pakistan were partitioned, creating a predominantly Hindu India and an Islamic state, Pakistan.

Chinese Nationalism

The history of modern nationalism in China is inextricably linked to the advent and increasingly severe threat of Western imperialism. Traditionally, Chinese rulers and intellectuals conceived their polity as a universal empire, primarily defined by culture and civilization rather than borders and ethnicity. With the arrival of the European powers, especially in the aftermath of the devastating defeat to the British in the Opium Wars (1839–1842 and 1856–1860), Chinese leaders started to accept the centrality of the nation-state within the realm of international relations. Under the direction of Prince Gong (1833–1898), the Zongli Yamen (the Office for the Management of the Business of All Foreign Countries) was opened in 1861 to handle negotiations with foreign powers. In the international arena China was moving, albeit haltingly, away from the universal empire model and toward that of the nation-state.

The opening of the twentieth century, however, proved that adopting European models of nation-state diplomacy would be easier than instilling a united sense of nation among the inhabitants of the Qing empire. While this difficulty was certainly based in China's status as a vast agrarian land inhabited by illiterate farmers, perhaps a more fundamental problem was defining "China" as a coherent entity. The Qing dynasty, founded by Manchus from the northeast, was considered by many ethnic Han Chinese to be an alien regime that had to be removed in order for China to develop as a modern nation. Thus, the radical intellectual Zou Rong (1885–1905) wrote *The Revolutionary Army* (1903), hoping to convince his readers

> NATIONAL DRESS

During the early twentieth century, traditional Chinese forms of dress were increasingly seen as inappropriate for a modern Chinese nation. But what forms of dress best suited a new China? For men, in the early twentieth century the most popular style of dress for elites was the *changshan* (long shirt), a long flowing robe that was usually paired with a short riding jacket. Due to the desire to express a more modern sensibility, Western styles became popular with elite men. But given the strong anti-imperialist leanings of the time, such Westernization was an ill fit for many Chinese. The fashion compromise was the Zhongshan suit, introduced by Sun Yatsen, commonly known as Sun Yatsen. A blend of Western and Chinese styles, it became the standard dress for Chinese leaders until the end of the Maoist era. Similarly, Chinese women faced a fashion dilemma during the early twentieth century. The dominant style of dress for elite women was a full jacket paired with a pleated skirt, under which was a pair of loose trousers. Much as had been the case with men, Western styles soon became the rage, but by the 1920s there was a sense that this style of dress was not appropriate for Chinese women. The result was the *qipao*, which took cues from Chinese garb but utilized a one-piece form that drew on Western fashion and emphasized femininity.

—Brian James DeMare

that the Manchus were bandit outsiders and responsible for the slaughter of countless Han Chinese during their invasion. For the young Zou Rong, China as a nation was synonymous with the Han Chinese ethnicity; any Han Chinese who dared to support the Qing rulers were considered traitors to their race and nation.

The disconnect between radicals such as Zou Rong and the vast population of agrarian China had already effectively been demonstrated in the 1901 Boxer Uprising. This pro-Qing uprising originated in the northern China plain during a period of drought and its resulting fears of famine. Linking the drought to the increasing presence of European (particularly German) missionaries, villagers lashed out violently against

the missionaries and their Chinese converts. Violent xenophobia meshed with local traditions of shamanism and martial arts, allowing the spread of the Boxers United in Righteousness across the northern China plain. The arrival of the Boxers in Beijing, where they carried out a lengthy siege of the foreign legation quarters, resulted in the dispatching of an expeditionary relief force by a number of Western nations. Significantly, Japanese troops joined the relief column, suggesting their future role as an imperialist power within China.

The failure of the Boxers and regular Qing forces to defend the capital from the relief force firmly underscored the weakness of the Qing regime. While the Qing rulers attempted to carry out reforms to strengthen the dynasty, each reform seemed to create more dissatisfaction with the conception of a Chinese nation ruled by the Manchu. The elimination of the Imperial Exam System (*keju*) in 1905, for example, destroyed the strongest bond between Chinese elites and the imperial state. With the 1911 Revolution, the imperial system was overthrown and replaced by a republican system of government, but the nascent Republic of China proved unworthy as a state for the Chinese nation. Soon China was divided among several warlords, most of whom were focused on retaining their own power as opposed to unifying China or resisting imperial aggression. It would be imperial aggression, however, that would inspire an ever-growing sense of nation among the Chinese people.

This was particularly the case with the May Fourth Movement of 1919, a moment when the frustrations of the Chinese nation were powerfully exposed. The movement, spurred by news that the Versailles Conference closing World War I had ceded the Shandong Peninsula to Japan, proved to be a crucial moment in the forming of a Chinese nation. While the main protesters were students and intellectuals, May Fourth leaders saw the importance of spreading their message of national liberation to as wide an audience as possible. Countless journals and newspapers were founded, with most of these publications focusing on building a “New China.” As the sense of crisis spread, new emphasis was given to Chinese culture, most notably literature but even cultural markers such as dress.

While the May Fourth generation looked down at the Boxers for their superstition, seeing them as emblematic of everything that was wrong with China, many Chinese still viewed them as nationalist heroes. In 1924, under the direction of Sun Yatsen, the day of the signing of the Boxer Protocol that had ended the uprising was transformed into an annual National Humiliation Day, suggesting the importance of imperialist aggression in creating a sense of nation for the Chinese people. Also in 1924, Sun Yatsen changed the national anthem for the Republic of China, introducing a new tune that stressed loyalty to his political party, the Guomindang (KMT). If imperialism had provided the spark for the spread of nationalism in China, the one-party state would provide the institution that would seek to contain and control Chinese nationalism.

By 1927 the Guomindang, now under the control of Jiang Jieshi (Chang Kai-shek), had a state that could provide direction to the Chinese nation. But the reach of the state was severely limited, and in the countryside life continued as it had during imperial times. Even in areas controlled by the Chinese Communist Party (CCP), the question remained the same: how to instill a sense of nation in the peasantry. The answer was provided with a new round of imperialist aggression, this time at the hands of the Japanese Army. With the outbreak of all-out war in 1937, the horrors of foreign aggression were brought home to an ever-widening number of Chinese peasants. This was particularly true in northern China, where an attempt to break the links between the communists and the peasantry through harsh military campaigns had the opposite effect, instead turning peasants into nationalists who saw the CCP as the one organization that could repel the Japanese.

The close of the Anti-Japanese War was quickly followed by the Chinese Civil War, and the CCP’s nationalist credentials from engaging Japanese troops were of no small importance in propelling them to victory. The ties between nationalism and anti-imperialism, as well as the linking of Chinese nationalism with a one-party state, would have important consequences in the post-1949 era.

Japanese Nationalism

Central to the formation of Japanese nationalism—more appropriately, ultranationalism during the period 1900–1945—was the Shinto myth that the emperor was a descendant in the direct line of the sun-goddess Amaterasu; that the Japanese people were also of divine descent, though from lesser gods; and that between the emperor and the people there was a mystical bond superior to anything of the kind to be found elsewhere in the world. From the turn of the twentieth century through the 1910s, three groups in particular—the Home Ministry, the Japanese Army, and the Ministry of Education—responded with initiatives to generate greater nationalism and greater loyalty to the state and to authority in general.

The Home Ministry took steps to dramatically reorganize the system of local government beginning in the 1890s. By the end of the Russo-Japanese War (1904–1905), the ministry ordered the nation's 76,000 small hamlets to merge into just 12,000 larger villages. Fewer villages, the government believed, would be easier to control from the center. The Home Ministry, for similar reasons, ordered the merger of 190,000 Shinto shrines—often tiny sites maintained by villagers in the absence of a priest—to just 12,000 officially recognized shrines as part of the state-administered Shinto network created in 1900.

The Home Ministry also sought to involve women as well as men in a variety of centrally

controlled bodies, such as rural credit societies, to promote a collective spirit under a central umbrella. In 1901, the ministry created a Ladies' Patriotic Association, and the group grew during the Russo-Japanese War to include 500,000 members nationwide. After the war, the Home Ministry drew together scattered local Gratitude Societies (Hotokukai) into a national network with official sponsorship. These groups had been founded in the early Meiji era (1868–1912) and honored the spirit of a famous agrarian moralist of Tokugawa times, Ninomiya Sontoku (1787–1856). A set of Women's Gratitude Societies was launched in 1907.

The Japanese Army, for its part, founded the Imperial Military Association (Teikoku zaigo gun-jinkai) in 1910. Its members were volunteers, recruited from among young men who had passed the conscription exam. By 1918, the group had branches in virtually every village in Japan and boasted over 2 million members. Its founders wished to raise military preparedness among men who might be called to active duty in an emergency. They also had a more general goal of reinforcing social order in turbulent times.

The Ministry of Education joined the drive to promote nationalism and respect for authority by adding two years to compulsory education in 1907. This helped to further stabilize school finances and to enforce curriculum shifts that emphasized nationalism and the role of the emperor more heavily. The ministry also boosted the status of teachers by stressing their role as national servants and local leaders.

In the early twentieth century, this wide range of government campaigns, implemented through the leadership of local elites, reinforced social order and central control. These campaigns sought to transfer peoples' loyalties away from independent social groups on the hamlet level and link them instead to groups on the village and town levels controlled by the state. By the time World War I came to pass, many ties bound the Japanese people to the state. In theory, these included the ties of dutiful soldiers in reserve associations, obedient wives and daughters in women's groups, respectful tenant farmers in gratitude societies or credit associations, pious villagers supporting local shrines, and earnest students in youth groups.

After World War I, the promotion of military fascism by Kita Ikki (1883–1937) as a panacea for Japan's social and economic ills became an important prelude to the rise of ultranationalism. He was also in favor of Japan's continental expansion policy, which eventually led to the creation of the Greater East Asia Co-prosperity Sphere. Of all of the extreme nationalists, none equaled Kita in influence. He was a dreamer in his youth, attaching himself to the revolutionary activities of the Chinese nationalists, and when its leader, Sun Yatsen, failed to live up to his promise of building an anti-imperialist, socialist state, the disillusioned Kita withdrew to Shanghai and wrote pamphlets advocating reforms of Japan.

Kita's *General Outlines of Measures for the Reconstruction of Japan* first appeared in mimeographed form in 1923. Even though it was banned in Japan, Kita was able to gain adherents among young military officers. He urged that the emperor suspend the Constitution and place the country under martial law. These measures, he argued, were intended to give the emperor complete freedom to suppress reactionary movements by the wealthy and their peers. Destruction of the status quo would be accompanied by the establishment of a socialist state that would control the national economy in the interest of the entire nation.

The appeal of Kita lay in his relentless attack, perhaps not justified, on the status quo symbolized by the oligarchy and private wealth. Since the beginning of modernization, the Japanese government consistently aided industry by imposing an undue tax burden on peasants and urban workers. While the rich became richer, many peasants and urban workers maintained living standards not much better than those of preindustrial days. Young officers, many of whom came from poverty-stricken areas, saw in Kita's outcry for reform a panacea for all ills. A close affinity was discernible between Kita's doctrine and several assassination attempts and military coups staged by young officers during the 1930s.

Kita was implicated in a revolt of February 26, 1936, and was executed along with other conspirators. However, his idea of internal reform and external expansion lived on and remained especially appealing for military officers.

The February 26 incident helped create a climate under which the Japanese government was forced to accept as its own the policies advocated by the army. At that point, Japan's ultranationalism became inseparable from its militarist policies.

Vietnamese Nationalism

A sense of national identity among Vietnamese during the first half of the twentieth century grew from their experiences with foreign colonialism. French forces completed their conquest of Vietnam in 1895, beginning a period of social and economic change. Vietnamese people, mainly urbanites, encountered new technologies and ideas that transformed their society. In the early twentieth century, participation in a new national political culture as citizens (*công dân*) rather than subjects of the king and an expanding public sphere changed Vietnamese lives, albeit within boundaries created by the French colonial administration.

The French introduced new industries to Vietnam; mining (mainly anthracite) and rubber plantations grew rapidly between 1924 and 1929. Some 200,000 Vietnamese people worked in deplorable conditions for low wages on rubber plantations in the Central Highlands; 90,000 factory workers and 40,000 Vietnamese miners of both genders had similar experiences. Peasants faced hardships working on colonial roads, railroads, bridges, and waterworks begun by Governor-General Paul Doumer in 1901.

Rice cultivation increased from 1.282 million acres (518,000 million hectares) in 1880 to

5.45 million acres (2.2 million hectares) in 1939; however, French export policies left less rice for individual households. Conditions hit bottom in 1944–1945; nearly 2 million people starved when the Vichy government, urged by the Japanese Army, which had seized control in 1941, increased rice exports, stockpiled rice, and produced large quantities of rice ethanol, resulting in major food shortages.

The Vietnamese countryside gradually converted to a cash economy, as the colonial administration levied head taxes, land taxes, conscripted *corvée* labor, and mandated salt and alcohol purchases from government monopolies at exorbitant prices. Salt prices increased fivefold between 1899 and 1909, while licensed alcohol prices were 900 percent above cost. Heavy taxation caused many small landowners to default; by the end of the colonial period a handful of people owned the majority of farmland.

Vietnamese officials sent to collect levies in the countryside were cursed, criticized, or assaulted by villagers unless protected by soldiers. Colonial rule reinforced traditional patterns of Vietnamese village solidarity; the destruction of evidence, the refusal to testify against fellow villagers, and more serious acts of resistance such as brewing contraband liquor and refusal to pay taxes in full were commonplace. In addition to economic conditions, general French disregard for Vietnamese people, such as when the resident superior of An Nam pillaged Emperor Tu Duc's tomb in 1913, drove radicalization of the Vietnamese population.

The quality of life for the more than 80 percent of Vietnamese people living in the countryside declined substantially under French rule. Education levels and literacy declined between 1880 and 1920, and only 13 percent of villages had a school in 1921. Traditionally, village teachers trained to take the Confucian civil service examinations; however, with the end of these exams in 1919 and difficult economic conditions, there were fewer people with the time to study. And though traditional arts such as *cheo* and *cải lương* stage remained popular, there was less time for artistic pursuits as people struggled to earn their living. Harsh conditions under colonial rule increased interest in Buddhism, Daoism, Catholicism, and traditional Vietnamese religious

➤ FRENCH VIETNAM

- 1895—Mandarin Phan Dinh Phung's resistance movement defeated by French colonial troops. All Vietnam now under firm French control.
- 1897–1902—Paul Doumer is governor-general. Expansive public works program undertaken.
- 1907—Tonkin Free School opened in Hanoi. Quoc Hoc Academy opened in Hue; students include future national leaders Ngo Dinh Diem, Vo Nguyen Giap, and Ho Chi Minh.
- 1914—More than 100,000 Vietnamese laborers and artisans were sent to serve France in World War I, where they were radicalized through their contact with European society.
- 1917—French Secret Police (*Sûreté*) reorganized with a large network of informants; Vietnamese elite put under surveillance.
- 1919—Bui Quang Chieu launches the Constitutionalist Party (*Dang Lap Hien*). State Confucian Examinations ended.
- 1927—Vietnamese Nationalist Party (*Viet Nam Quoc Dan Dang*, VNQDD) organized.
- 1930—VNQDD under Nguyen Thai Hoc lead major uprising in Yen Bay, 70 miles (113 kilometers) north of Hanoi.
- 1931—Vietnamese communists lead uprisings in Nghe An and neighboring Ha Tinh provinces.
- 1936—French Popular Front government abolishes censorship in Indochina.
- 1937—Nationwide Association for the Dissemination of Quoc Ngu Study organized. Widespread literacy classes offered to 59,827 students by 1944.
- 1941—Japanese Imperial Army seizes control of Indochina and governs through the Vichy French regime.

practices. Two new major sects, the syncretic Cao Dai and Huynh Phu So's Hoa Hao Buddhist sect appeared and grew rapidly in the colonial era. At the same time, new technologies introduced by the French, such as bicycles and electric lights, brought a wider world to villagers in a limited way. Public health and sanitation improved with the widespread availability of soap and increased construction of Western medical facilities, while the explosion of urban print culture began to slowly expand rural Vietnamese perspectives.

In Saigon and Hanoi, Vietnamese society underwent significant changes between 1900 and 1930. Most of the 20,000 resident French in Vietnam lived in one of the two major cities, and so Western cultural influences were at their strongest in these two areas. Many urban Vietnamese people adopted Western dress and language, while cuisine and social behaviors were influenced by the French presence. In the 1920s a growing middle class—composed of groups such as merchants, clerks and secretaries, technicians, schoolteachers, and journalists—and an urban elite that included many who imitated French habits, learned the French language, and adopted popular French pastimes such as tennis and soccer took part in a nationwide scouting movement, went to newly built beach resorts, read Western literature, bought bicycles or motor scooters, and in some cases studied in France. French influence on Vietnamese print and intellectual culture was particularly strong; the Confucian-dominated scholarship of the past gave way to Western-influenced alternatives that ultimately undermined the French colonial project.

Members of the Vietnamese elite, such as Nguyen Van Vinh, who collaborated with the French, and later communist leader Vo Nguyen Giap worked to expand literacy and to popularize the use of the Romanized national script, Quoc Ngu, in place of the earlier system based on Chinese characters, Chu Nom. This change made the Vietnamese language a great deal easier to learn. In the 1930s and after, literacy movements were launched that reversed the declining literacy of prior decades; by 1939 approximately 1.8 million, or 10 percent of the Vietnamese population, attained literacy, often taught by friends, relatives, or members of the growing Vietnamese political parties. These movements continued the work of the Tonkin Free School in Hanoi and Ngo Dinh Kha's Quoc Hoc (National Study) Academy in Hue city in the first decade of the twentieth century.

The Vietnamese public sphere grew substantially in cities after 1907; the numbers of publications in Quoc Ngu grew rapidly between 1920 and 1930, covering diverse subjects such as politics, women's rights, hygiene, the value of Westernization, the question of Vietnamese independence, the role of Vietnamese tradition in

the changing society, and large amounts of more traditional publications on religion, moral behavior, and popular fiction. Vietnamese political leaders, visual artists, and authors were conflicted by decisions about how and whether or not to combine traditional and Western forms of expression throughout the colonial era.

Readers of publications such as *Phu Nu Tan Van* (*Women's News*) and Nguyen An Ninh's *Le Cloche Felee* (*The Broken Clock*) encountered ideas and literature from notable Vietnamese and Western authors that contributed to the awareness of colonial life's shortcomings. For example, in 1937 there were only five Vietnamese medical doctors employed by the National Health Service. Vietnamese people were further constrained by the pervasion of collaborators and French Secret Police informants and state restrictions on travel. Vietnamese participation in labor unions and various political parties increased substantially, from Bui Quang Chieu's Constitutionalist Party and the Vietnamese Nationalist Party based on China's Guomindang to the Indochinese Communist Party of the then little known Ho Chi Minh.

Latin American Nationalism

Nationalism as a common identity that all citizens of a nation or region could relate to did not develop fully in Latin America until the early twentieth century. Identities based on ethnicity such as Spanish, Creole, Indian, mestizo, or

black were much more prevalent during most of the region's history than were national or regional associations. A restrictive racial and class hierarchy that caused friction and isolation prevented the formation of a cohesive sense of unity. Nationalism first emerged during the independence wars from Spain and Portugal (1810–1825) as Creoles in the colonies used nativism to promote patriotic sentiments. Nativism, the notion that colonialists shared an identity with each other that was separate from that of those born in the motherland, was seen as a means to unite the population in the fight against Spain and Portugal. However, in reality the elite Creoles who had instigated the independence movements had more in common with the colonialists they were fighting than with the indigenous, black, and mestizo population. It is therefore not surprising that these nationalistic sentiments subsided soon after independence, leaving the colonial order intact with the white minority holding economic and social power.

The development of a common identity was further hampered by the infringement of foreign powers on the region soon after their independence from Spain and Portugal. North American and European investments, exploitive trade relations, and military interventions led to economic dependency and an encroachment on the region's sovereignty. Turn-of-the-century emphasis on progress exasperated divisions in the population. The stress on urbanization as a means to meet Western standards of modernity alienated Latin Americans living in the countryside. Official racism supported by Social Darwinism reinforced the racial hierarchy, denigrated the region's indigenous and African heritage, and further polarized Latin Americans. Furthermore, cultural emulation of the United States and Europe hampered the development of a distinctive and valued Latin American culture.

Turn-of-the-century modernization projects geographically and socially transformed many Latin American capitals, among them Havana, Buenos Aires, and São Paulo. Urbanization fostered the growth of an educated middle class that rejected the social hierarchy of the early republic, one that had changed little since the colonial era. Middle-class professionals throughout Latin America, among them Mexico, Cuba, and Brazil,

➤ DIEGO RIVERA

Born in 1886, Mexican Diego Rivera became a world-renowned muralist in the 1920s and 1930s. His work is exemplary of the nationalist movement in Mexico in that it was about, and for, the Mexican people. As a means to expose his art to the majority of the population and not just the rich, Rivera painted massive murals in public buildings. His highly politicized work addressed historical and social issues of oppression. He often incorporated themes relating to the exploitation of the indigenous and mestizo population, including those of the Aztecs during the conquest and contemporary Mexican workers and peasants. Furthermore, his nationalistic emphasis brought to life many of the revolutionary themes of the Mexican Revolution. The controversy surrounding Rivera was often tied to his inclusion of communist symbolism and messages in his murals. Nevertheless, as a prominent artist he called attention to the plight of poor Mexicans and gave credence to the existence of a distinctive Latin American culture.

—*Lizabeth Martinez-Lotz*

spouted nationalist rhetoric, demanded social reform, and rejected U.S. imperialism. Their reformist agenda calling for a more inclusive social system had wide appeal among the lower classes. In Mexico, peasants took these messages of nationalist reform to heart by fighting a revolution that lasted for nearly two decades. The Mexican Revolution garnered nationalistic sentiments throughout Latin America by provoking a desire for governments that served the masses. Political leaders calling for economic reform and public welfare programs gained popular support throughout the region. Numerous nationalist governments came to power during the first half of the twentieth century. Batlle y Ordóñez (1903–1907, 1911–1915) in Uruguay, Cárdenas (1934–1940) in Mexico, and Vargas (1930–1935) in Brazil are among the more notable nationalist presidents of the region. These nationalist governments made drastic economic changes, including nationalizing public utilities, banks, and industries; passing tariffs to protect small businesses; and promoting industrial development. The break from economic dependency and

underdevelopment became possible after the Great Depression with the immediate decline in international trade. It was only then that import-substitution industrialization, the manufacturing of goods for internal consumption, became a reasonable and realistic goal.

Nationalism was not simply a political movement; in fact, it had a great social and cultural impact on Latin American society. In cities throughout the region, social issues such as education, welfare programs, and women's suffrage were at the forefront of public policy and intellectual debates. The desire to create a modern and sovereign nation for all its citizens generated discussions on nationhood. It became necessary to cultivate national identities that were distinctive in and of themselves and not simply in opposition to North American and European imperialism. A rejection of their racial identity and a desire for whitening (socially passing as white by means of upward mobility through marriage, education, etc.) had led to a divided Latin American society. It therefore became imperative under nationalism for Latin Americans to not just accept their mixed race heritage but embrace it. *Indigenismo* and Afrocentric movements developed as the region celebrated its synthesis of Spanish, Indian, and African culture. Nativism in art, literature, music, and dance was a breakaway from North American and European measures of culture and a creation of distinct Latin American styles. Folk art, costumes, music, and dance became stylish, not only within Latin America but also internationally. Artists, musicians, and writers attained international acclaim by calling upon their indigenous and African heritage. Notable among them are Mexican muralist Diego Rivera, Mexican painter Frida Kahlo, Cuban novelist Alejo Carpentier, Peruvian novelist Ciro Alegria, Guatemalan novelist Miguel Angel Asturias, and Brazilian classical composer Heitor Villa-Lobos. The success of nationalism in fostering a distinctive Latin American cultural identity did not by any means eradicate racism. The goal of whitening was no longer publicly embraced, but social status and economic power were still largely based on ethnicity. Furthermore, industrialization, nationalist governments, and urbanization did not develop in all regions of Latin America. And in the sec-

ond half of the twentieth century, many of the benefits of nationalism seemed to dissipate as grave problems arose as a result of overpopulation in urban centers, unemployment, and unsuccessful industrialization.

Pan-Slavism

The oldest of the macronationalist movements, Pan-Slavism has never been a coherent or distinct ideology and has never had a stable organizational structure. Pan-Slavism has been constituted instead by a rough grouping of ideas calling for cultural unity among Slavic peoples. Yet despite its appeal to unity across national boundaries, the movement has never attracted a very large following. Although initially intended to draw Slavs together, Pan-Slavism eventually took on extremist characteristics and, on the whole, has been politically unsuccessful.

The origins of Pan-Slavism are tied in many ways with the work of Johann Gottfried von Herder (1744–1803), a German intellectual and a prominent figure in the Romantic movement. Herder was influential in the formation of German national consciousness, in part by asserting that language was critical to the development of a sense of national identity. Although Herder's work was important to German nationalism, it also helped shape the emergence of Pan-Slavism. In his *Ideas for the Philosophy of the History of Mankind*, Herder praised the Slavs for their peaceful disposition and their love of music and literature. A follower of Jean-Jacques Rousseau, Herder contrasted the idyllic rural life of the Slavs with the artificial urban life of Germans. Herder's work detailed how the Slavs had been oppressed by German wars against them and argued that the Slavs would again rise to greatness

in the nineteenth century. He encouraged Slav intellectuals to study their own language rather than adopting French or German and also urged them to collect the folklore and folk songs of their culture to develop their own history. Herder hoped that with a fuller appreciation for their own history and language, the Slavs would unite and work to improve the human condition.

Although Herder's work was idealistic and lacked any particulars about how best to achieve unity, his glowing assessment of Slavic culture inspired many Polish, Czech, and other Slavic intellectuals to direct their efforts toward unification. The first notable proponent of this new Pan-Slavism was the Czech historian and politician Frantisek Palacky.

Influenced by Herder, Rousseau, and Immanuel Kant, Palacky called for the establishment of independent and equal Czech nations within the Austrian empire that would counterbalance German and Russian influence. Palacky was concerned about German expansionism, Russian domination, and expanding Magyar nationalism, and thus he argued for Slavs in the Austrian empire to take a leading role in determining their own future. Although Palacky supported several proposals for Slavic federation within the Austrian empire, none came to fruition in his lifetime.

Palacky did, however, take part in some of the major events during the emergence of Pan-Slavism, most notably the Pan-Slavic Congress at Prague in 1848. At Palacky's invitation, 341 delegates gathered in Prague to encourage cooperation among all Slavs. Following the revolutions of 1848 that swept across Europe, the meeting had the advantage of a progressive and hopeful context. The primary aim of the congress was to unify western Slavs (i.e., Czechs, Moravians, and Slovaks), eastern Slavs (i.e., Poles and Ukrainians), and southern Slavs (i.e., Slovenes, Croatians, and Serbians). Although intended to include all Slavs, the congress was not attended by many non-Austrian Slavs, including Russians and Bulgarians. The absence of the Russians would prove to be especially problematic, and the congress eventually took on a distinct anti-Russian tone. After some debate, the congress issued three declarations—one to the Austrian emperor, one to all Slavs, and one to European nations—all more or less asserting the democratic rights of Slavic peo-

ple and their desire to live in peace and equality with other nations. Those statements, however, produced few discernible results, and deep fissures persisted among the diverse Slavic groups. The major accomplishment of the congress was to move Pan-Slavism from an idealistic philosophical perspective to a distinctly political movement dedicated to furthering the goals of Slavs.

The Russians were very unhappy after being excluded from the Prague Congress, and many involved in Pan-Slavism believed that the movement should be unified under the leadership of Russia, which was, after all, the largest and strongest Slavic nation. The czarist Russian government favored that position, and Russia itself had its own precursor to Pan-Slavism, known as Slavophilism. Like Pan-Slavism, Slavophilism was influenced by Romanticism and called for a return to past religious, cultural, and political traditions. Unlike Pan-Slavism, though, Slavophilism was anti-Western in its orientation and resisted the role of reason over emotion that prevailed in western European thought. Slavophilism also had a strong religious component and argued for Russia to assert itself as the only home for the one true religion, orthodoxy. For Slavophiles, Russians were clearly God's chosen people, who stood in sharp contrast to Westerners corrupted by materialism. Slavophilism thus undergirded the aggressive and expansionist form of Pan-Slavism developed in Russia that called for a unified Slavic nation running from the Baltic Sea to Constantinople and governed under Russian leadership. The two most prominent advocates for that kind of Pan-Slavism in Russia were the anti-Darwinist scientist Nikolai Yakovlevich Danilevsky and the famous novelist Fyodor Dostoyevsky.

With the development of a different strain of Pan-Slavism in Russia and splits within the previously dominant form of Pan-Slavism, leadership of the movement shifted toward Moscow in the early 1860s. In 1867 the Society of Friends of Natural Science at Moscow University organized a meeting of various Slavs that became the Second Pan-Slavic Congress. Several non-Russian Slavs were invited and attended, including Palacky, but Poles were excluded. As in the first congress, splits emerged in the second congress, most notably between the Russians and all other Slavs. The Russians insisted that Russian become

the official language of all Slavs and argued that Russia had created the Polish nation, which meant that it could never be independent. While other Slavs argued for mutuality and equality among all Slav nations, Russians saw Pan-Slavism as a movement for the supremacy of orthodoxy, the Russian language, and Russian culture. As in Prague, the differences within and confused goals of Pan-Slavism meant that the Moscow congress produced few practical results. Although plans were made for the next congress to be held in Belgrade in two years, the next Pan-Slavic meetings were not held until the early twentieth century.

The internal divisions of Pan-Slavism in the final decades of the nineteenth century led the movement to stall. Although Pan-Slavism thrived in Russia, opinions about the movement in the Balkans were deeply divided over the role of Russian influence. Some resented the fact that Pan-Slavism had basically become the doctrine for Russian imperialism, while others looked to Russia for guidance. In Poland, Pan-Slavism was threatened by the Pan-Polish ideal that called for a larger united Polish nation. The Czechs, however, continued to keep the earlier strand of Pan-Slavism alive and saw it as an effective counter to German expansionism. Karel Kramar, a Czech politician, promoted a more liberal form of Pan-Slavism called Neo-Slavism. The next Pan-Slavic Congress was held in Prague in 1908, followed by another in Sofia in 1910. As in past meetings, divisions among Slavs made progress virtually impossible. At the same time, the Russians held their own meeting in 1909. Pan-Slavism was then overshadowed by the Balkan Wars of 1912–1913, which pitted Slavic nations against each other.

The end of World War I brought the fulfillment of some of the demands of the early Pan-Slavism movement, namely the establishment of three new nations: Czechoslovakia, Poland, and Yugoslavia. Yet the states themselves were fairly weak, and rivalries persisted among them. The apparent decline of Pan-Slavism was underscored by the Russian Revolution of 1917, and the new Soviet government denounced Pan-Slavism as reactionary ideology.

Although Pan-Slavism seemed dead, it was resurrected by the Soviets themselves in the 1940s as a way to unite Slavs against the Nazi re-

gime. Pan-Slavism conferences were held in Moscow during World War II. Congresses for people of Slavic descent were also held in North America and South America during the war in an effort to find ways to support the struggle of Slavs in Europe. After the war, the Soviets continued to invoke Pan-Slavism and sought to merge it with their communist ideology. Like other Pan-Slavic efforts of the past, however, that effort failed to unify the Slavs, as splits arose between Josef Stalin and Yugoslavia's Josip Broz Tito.

For the most part, however, Pan-Slavism has been unsuccessful in achieving its political and cultural goals. The Slavs are geographically separated, and different Slavic groups have had very different historical experiences. The religious differences among Slavs are also substantial; the rift between Roman Catholic Slavs of the west and Orthodox Slavs of the east runs very deep. Most problematic, however, the transformation of Pan-Slavism into simply a synonym for Russian and Soviet political ideologies has limited its appeal to Slavs of other nations. All of those factors combined have meant that Pan-Slavism has been unable to achieve the goals of Slavic unity and liberation articulated so eloquently in the early nineteenth century.

Indonesian Nationalism

At the turn of the twentieth century, the Netherlands East Indies was an odd imperial entity. Rapid territorial expansion in the second half of the nineteenth century had brought together a wide array of islands and populations that had little in common apart from their Dutch colonial

masters. Even on the island of Java, the economic heart of the East Indies with the largest population, differences in ethnicity, religious outlook, language, regional identity, and strong social differentiation made it unclear on what basis a nationalist project might be successful. Eventually, territorial nationalism aiming to capture the territory of the colonial state, rather than ethnic nationalism aiming to unite an ethnic group with a common history, would emerge.

Those opposed to Dutch domination realized that earlier models of anticolonial action (usually conservative with the aim of restoring the old feudal order, an Islamic polity, or a millenarian society) failed to provide a good guideline for independence. They had generally been localized and unsuccessful, whether led by sultans and rajas, or ulamas and other leaders. Modern technologies offered the promise of the invention of new organizational vehicles and symbols, and the exploration of novel ways of communicating and coordinating collective action. Yet the social construction of a new political community remained a tortuous process.

Under the initially benevolent eyes of the colonial administration, which in 1901 had adopted what was popularly termed the “Ethical Policy” that aimed to provide a modicum of welfare and education to the “natives,” various organizations began to blossom. Key figures in this elite- and reform-driven “national awakening” were Dutch-educated “natives,” Javanese batik entrepreneurs, devout modernist Muslims, Eurasians, and some Dutch socialists. Given the restrictive political space permitted by the Dutch colonial state, most of these organizations aimed for political or socioeconomic reforms, though some articulated plans for eventual independence and radical change. Three broad and sometimes interconnected streams were to emerge: Islamic reform, Socialism-Marxism, and secular nationalism.

The official genealogy of modern reform usually begins in 1908 with the Budi Utomo (Noble Endeavour), an organization set up by Dutch-trained students, many of them from the Training School for Native Doctors (STOVIA). Their ambitious plans for social reform in Java, and eventually on other islands, quickly ground to a halt when the organization was taken over by

more conservative members of the aristocracy dedicated to the preservation of Javanese values.

More successful were Javanese batik traders who in 1912 established the Sarekat Islam (SI). Within a very short time, the organization had set up branches throughout Java and beyond and would soon claim a mass following of several hundred thousand to two million. A catch-all movement that tried to appeal to the rural masses, whether the more purist Islamic *santri* or more syncretic *abangan*, but also to conservative and reform-minded aristocrats, the SI opted for a cooperative rather than a confrontational approach. Among its key leaders was Raden Umar Sayed Tjokroaminoto (1882–1934), a charismatic Dutch-trained aristocrat regarded by many Javanese as the *ratu adil* (just king). This did not go unchallenged by other SI members who favored a reformist and modernist Islam. Also founded in 1912 was the Muhammadiyah, another Islamic reform movement that largely preferred social reforms rather than nationalist activism.

Far bolder were the leaders, many of them Eurasians, of the short-lived Nationale Indische Partij (1912) who demanded socioeconomic justice, and racial equality, and explicitly asked for eventual independence of the Netherlands East Indies. The organization was wrapped up by the colonial authorities within a year and its top leaders Ernest Douwes Dekker (1879–1950), Suwardi Suryadiningrat (1889–1959), and Tjipto Mangunkusumo (1884–1942) temporarily exiled in the Netherlands. Repatriation or prison was also the fate of the leaders and activists of the Indies Social Democratic Association (ISDV), which had been set up in 1914 by Dutch socialists under the leadership of Hendricus Sneevliet (1883–1942), after it had instigated Dutch sailors and soldiers in Surabaya to mutiny and form soviets (workers’ councils).

The ISDV nevertheless survived and gained a foothold among the native masses through membership in the SI. After transforming into the Communist Party of Indonesia (PKI) in 1920 and a leadership challenge to the SI, the PKI managed to take over half its membership. A series of strikes in 1925 led to a crackdown on the party and the exile of party leaders such as Tan Malaka (ca. 1896–1949). Despite this setback, a

series of Communist revolts erupted in 1926 and 1927, most severely affecting areas in Bantam (West Java) and Minangkabau (West Sumatra). Leaders who escaped the resulting crackdown fled overseas or went underground, only to re-emerge in 1945.

In contrast, the Indonesian Nationalist Association (PNI), formed in 1927, articulated a secular nationalist alternative to Islamic reform and Communism. Upon the initiative of the Study Club of Bandung, of which the recently graduated engineer Ahmad Sukarno or Sukarno (1901–1970) was a member, its membership included politically talented Netherlands-trained members such as Mohammad Hatta (1902–1980) and Sutan Sjahrir (1909–1966) and a younger generation of more confrontational students who had become politicized in the East Indies' study clubs. When Sukarno's speeches for what had by then become the Indonesian Nationalist Party (PNI) became increasingly incendiary, the authorities detained him and others in late 1929. The PNI dissolved in 1931, and successor organizations were short lived or ineffective after further Dutch repressions against noncooperating organizations. By the mid-1930s, Governor-General Bonifacius Cornelis de Jonge confidently stated that it would take another three hundred years to grant some autonomy.

The legacy of the late 1920s' nationalist movement was an agreement on nationalist symbols such as a red-and-white flag, an anthem entitled "Indonesia Raya," the advocacy of Indonesian (based on the archipelago's lingua franca, Malay, rather than Javanese or Dutch) as the nationalist language, and a new name for the Dutch East Indies and its capital Batavia: Indonesia and Jakarta, respectively. The Youth Pledge (*sumpah pemuda*) of the second Indonesian Youth Congress of 1928 hence exhorted the "sons and daughters of Indonesia to acknowledge one motherland," "one nation," and to "respect the language of unity, Indonesian." The First Indonesian Women's Congress of December 1928 also made it clear that women wanted to be part of the Indonesian nationalist project.

By this time, Dutch hopes to contain indigenous political aspirations through the Volksraad (People's Council, 1916–1942), a multiracial uni-

cameral parliament comprised mostly of conservative Indonesians frequently with a civil service background, as well as Europeans and "foreign orientals" had largely failed. As the Governor-General was not accountable to it, the Volksraad had extremely limited power and hence offered little prospect of any significant change in the colonial relationship. With immunity guaranteed to the Volksraad members, some were encouraged to articulate the grievances and hopes of the population after the last noncooperative organizations had been emasculated. The last serious attempt in the Volksraad, a 1936 petition initiated by Sutardjo Kartohadikusumo toward self-government in a Dutch commonwealth was rejected two years later, thus seriously weakening any Dutch chances of prevailing against Japanese imperial ambitions.

The Japanese occupation of the Dutch East Indies in the first half of 1942 gave new lease of life to Indonesian nationalist aspirations. The defeat of the Dutch by an Asian power was psychologically important, and various Japanese policies allowed for a reawakening of Indonesian nationalism. Key leaders such as Sukarno, Hatta, and Sjahrir were liberated and the former two participated in a Japanese-Indonesian advisory council, Putera. Japanese-sponsored propaganda events gave in particular Sukarno the opportunity to address mass rallies in major Javanese cities. In addition the Japanese gave the archipelago's Muslims a voice by sponsoring the formation of Masjumi, the Consultative Council of Indonesian Muslims. In 1943, Japanese officers set up a paramilitary group, the Defenders of the Fatherland (PETA), and also encouraged the mass mobilization of youth, the "pemudas," both of which would feed into the armed nationalist resistance against reimposition of Dutch colonial rule. The Japanese surrender of 1945 and the resulting power vacuum gave Sukarno and Hatta the opportunity to proclaim Indonesia's independence only a few days later on August 17, 1945, thus opening a new chapter in Indonesian history in which not only the Dutch but also ethnonationalist and Islamic movements would challenge the secular territorial nationalism of the Indonesian Republic.

■ Introduction: Workforce and Workplace

In the period 1900–1945, larger segments of the world's population shifted from agricultural to industrial labor. Efforts to standardize labor via scientific management and other efficiency regimens extended from the workplace to regimented education systems offered to larger segments of the population. At the same time, industrial growth propelled the development of a clerical labor force and a managerial middle class. As occurred throughout the nineteenth century, in the period from 1900 to 1945 numerous strikes, often violent, broke out worldwide as workers sought better wages and working conditions. Ironically, the creation of the Soviet Union led to the decline of the union in that nation as an effective agent of change; centralized planning and propaganda that heralded the heroism of the laborer did not make up for grueling working conditions or quotas. In the 1930s, unions such as the American Federation of Labor (AFL) gained strength in the United States when the New Deal's National Industrial Recovery Act recognized union organizing, strikes, and collective bargaining as legal tactics. Some white-collar trades also unionized in this period, with the creation of unions such as the American Newspaper Guild and the British Railway Clerks Association.

In this period, the efforts of unions, labor activists, and journalists prompted many legislative efforts to enforce workplace safety, particularly in dangerous trades such as mining and railroads. Industry representatives tended to make the argument that the burden was on the worker not the employer for ensuring safety. As a consequence, work safety in industrial occupations was abysmal, though small gains were made during this period.

Both world wars offered new employment opportunities to women, as the war efforts drained industrial manpower. African Americans also made gains when protests led by union organizer A. Philip Randolph led to Franklin Delano Roosevelt's decision to issue Executive Order 8802, which required firms with federal contracts to hire interracial workforces. Forced labor was also a way of life throughout this period, whether in some forms of forced prostitution, in the prison chain gangs common in the southern United States, in the coolie labor system in the British empire that continued to contract for Asian indentured servants to labor in colonial outposts through World War I, in the Gulags in the Soviet Union, in the forced labor of Japanese prisoners of war,

or in the work and death camps set up under Nazi Germany's control.

—*Fred Nadis*

Post-World War I Growth in White-Collar Labor

When World War I came to an end in November 1918, white-collar workers across the industrialized world found themselves in a changed environment. Though differences existed at the national level, several general trends mark this period. Both government- and service-sector bureaucracies expanded significantly in the interwar period, increasing both the size and importance of the white-collar workforce. Labor agitation during the war led to a more favorable institutional and cultural situation, allowing for greater union activity. In spite of these shifts, however, industrial (or blue-collar) unions made significantly greater advances in comparison to their fellow white-collar workers. Increased unionization secured collective bargaining rights, which in turn raised wages and improved working conditions.

► WHITE-COLLAR IDENTITY

One of the interesting issues in the literature concerning white-collar workers centers on the status and deskilling of the workforce. As the service sector grew, an increasing number of unskilled jobs became available. Workers who no longer enjoyed the economic or social benefits historically associated with white-collar status filled these jobs. Historians and sociologists continue to engage in debate over how long this trend existed and how it impacts perceptions of class and social position. Such issues have a particularly important impact on the nature of white-collar unionism. Over time, greater connections between white- and blue-collar unions often homogenized the working-class movement, blunting the distinctions between the two groups. Further complicating the issue is the tension between class and gender, as female white-collar workers face increasing marginalization.

—*Tavis Harris*

One of the chief reasons white-collar workers fell behind the manual sector was a general resistance to organizing. During the interwar period, service-sector employees commonly enjoyed a higher degree of education or specialized skills training, which led to perceptions of distinctiveness and superiority as compared to laborers. In general, white-collar employees were more likely to identify with management and have a clear sense that career advancement was possible without recourse to organization. Given this sense of superiority, white-collar workers were generally hesitant to associate themselves with laborers. Several early white-collar unions structured themselves as professional associations rather than trade unions, often resisting efforts by groups such as the American Federation of Labor (AFL) or the Congress of Industrial Organizations (CIO) in the United States. This resulted in a lack of effective organizational capacity, and lacking wider support several fledgling white-collar unions were easily quashed by management. Connecting white-collar issues with the wider working class was a slow process that only came to the fore after World War II. However, throughout the 1920s and 1930s, white-collar workers increasingly realized that at least they shared common interests, and organization earnestly began.

The unionization of white-collar workers was significantly lower in numbers than trades or unskilled laborers, although government employees, clerks, and railway workers began to organize in significant numbers. This was especially prevalent in businesses where white- and blue-collar workers intermingled, thus illustrating the benefits of unionization. For example, unionized blue-collar workers often managed to secure better conditions and higher pay than the more socially prestigious clerical staff.

In spite of these structural and ideological issues, several lasting white-collar unions were created in the interwar period. In 1933 the American Newspaper Guild (ANG) was founded in Chicago. After early difficulties, the ANG moved toward a trade union model, associating with the CIO and partaking in a bitter struggle with the Hearst newspaper chain over issues of overtime and pay. Though formed in the late nineteenth century, the British Railway Clerks'

Association (RCA) enjoyed significant growth after 1918, as the majority of railway clerks supported the RCA as it pushed for industry-wide representation of clerical workers. Strike action secured this right, and the RCA continued to pressure management for better pay and working conditions throughout this period. The white-collar sense of respectability remained, while their unions increasingly reflected trade union tactics such as a series of white-collar strikes that plagued both the British government and employers in the interwar years.

Unionism

By the turn of the twentieth century, unions in the same trades and industries across the globe came to see themselves as sharing similar interests and experiences. As such, these labor organizations united in International Trade Secretariats (ITs) to further their interests in a world that was becoming increasingly internationalized. ITs emerged among employees in a wide range of occupations including boot and shoe workers (1889), clothing workers (1893), diamond workers (1905), and hairdressers (1907), among others.

Most of these secretariats' national affiliates were socialist in orientation, as were the ITs that called for replacing capitalism with socialism. However, the majority of the secretariats' work was pragmatic and focused on improving the wages and working conditions of the world's workers through activities such as distributing information concerning wages and working conditions, thwarting intercontinental strikebreak-

ing attempts by employers, and providing financial support to unions during periods of intense industrial conflict. By 1914, nearly 30 ITs had been established, with the majority of them headquartered in Germany.

In August 1901 the International Secretariat of National Trade Union Centres (ISNTUC) was created among largely European trade union confederations in order to encourage the formation of national federations throughout the industrialized world. Upon the recommendation of the American Federation of Labor (AFL) in the United States at the ISNTUC's last conference prior to World War I in 1913, the ISNTUC unanimously changed its name to the International Federation of Trade Unions (IFTU). The war, however, seriously hampered international trade union unity, with the labor movement of each country patriotically supporting its own government's war efforts. Thus, it was not until after the war's conclusion (1919) that the IFTU was reconstituted.

Nevertheless, a second rupture in the unity of the international labor movement occurred with the formation of the Red International of Labor Unions (RILU) when delegates from 38 countries met in Moscow in 1921. Motivated by the 1917 Russian Revolution, the RILU was a communist-led trade union international organized to lead the global proletariat in overthrowing capitalism in a manner similar to that adopted by the Bolsheviks. While expressing implacable hostility to the IFTU and its members, the RILU affiliates, which, for the most part, represented minority movements within their own national trade union federations, worked within the latter organizations in order to capture them for the RILU.

By 1928 the RILU argued that the national trade union federations had become social fascist and advocated the creation of revolutionary dual unions under communist control when and where possible. However, with the ascendancy of Nazism in Germany in 1933 and the threat of fascism's expansion to other European countries during 1934–1935, the RILU called for the abandonment of their revolutionary unions and a return to working within the national trade union movements in order to create united fronts between communists and socialists in defending the trade unions and political democracy within

the industrialized capitalist countries. After an IFTU delegation visited Moscow and rejected the RILU's demands for fusion in November 1937, the RILU was formally dissolved on December 27, 1937.

From 1919 to 1939 the IFTU hoped to utilize parliamentary democracy in combination with trade union action as the methodology for establishing socialism. Nonetheless, for all practical purposes, it sought to improve the lives of union members and workers by ameliorating the worst aspects of capitalism through the passing of protective labor laws, the reduction of working

hours, and the fight to end unemployment. The IFTU also called for the introduction of industrial democracy through the creation of national economic councils with trade union participation as well as factory and shop councils. The IFTU's 1939 congress in Zurich, during which it adopted motions opposing war and fascism, became its last.

Upon the end of World War II, the international trade union movement was united once more with the formation of the World Federation of Trade Unions (WFTU) in Paris in October 1945. At the founding congress, statements were

issued denouncing fascism, war, colonialism, discrimination, and racism, while proposals were made for extending unions' rights, improving working and living conditions, and restricting and eliminating monopolies. This unity, however, was short-lived due to programmatic differences between the Western trade unions and the communist-led union federations, leading to the formation of the Western-led International Confederation of Free Trade Unions (ICFTU) in 1949 by the noncommunist federations. The WFTU and the ICFTU remained divided due to ideological differences, as represented by Cold War thought that came to dominate political discourse throughout much of the second half of the twentieth century.

Industrialization and the Working Class

By 1900, the process of industrialization had reached maturity in western Europe and North America but was just emerging elsewhere. In the United States, the world's most industrialized nation, new organizational developments led to further production gains in the early years of the century. At the same time, every industrialized country inundated their satellite countries and possessions with technology to help extract natural resources. A few countries like Russia, Italy, and Japan greatly improved their economic position through rapid industrialization. However, two world wars and a global depression

➤ EMPLOYEE-REPRESENTATION PLANS

Employee-representation plans were organizations created by employers to stave off the spread of trade unions in their facilities. Known as company unions in the United States because many were management-dominated, these organizations became a means for employers to improve workers' lives in response to the unfavorable conditions that industrialization created for workers around the world. The first employee-representation plan to receive worldwide attention was the Rockefeller Plan at the Colorado Fuel and Iron Company. Championed by John D. Rockefeller Jr., it spread quickly to Canada through the Rockefeller-owned Imperial Oil Company. In Britain, a government commission proposed the creation of similar organizations, known as Whitley Councils, during the First World War. The United States banned company unions in 1935, but other industrialized countries remain friendly to the idea of communication through such organizations in the workplace to this day.

—Jonathan Rees

changed the course of economic development nearly everywhere.

Because industrialization spread unevenly throughout the world during these years, the working-class response to it varied greatly. In many places working-class concerns were intimately connected to the politics of the time, whether it was the nationalization of industries in the Soviet Union or the Roosevelt administration's decision to pass the National Labor Relations Act in 1935. The success of governments at quelling discontent over the effects of industrialization depended largely on their system of government and the extent of the threat to the survival of any particular nation.

Two figures greatly affected the course of American industrialization during this period: Henry Ford and Frederick W. Taylor. Ford's assembly line in 1914 popularized the idea of mass production, which brought down the cost of automobiles and other products whose manufacturers became influenced by Ford's vision. The ability to buy consumer goods at cheaper prices helped limit the dissatisfaction of middle-class

workers in the United States and other developed nations. Taylor, like Ford, was influential all over the world. Taylor's vision of scientific management led to considerable strife among skilled workers who did not like losing control over the production process. This is best symbolized by the famous 1911 strike at the Watertown Arsenal in Massachusetts, but many workers upset by the standardization associated with Taylor's ideas were probably too frightened of losing their jobs to protest in this manner.

When World War I broke out, West European countries were just beginning to emulate the American model of industrialization. The Krupp Steel Works and the Linde Company (in the chemical industry), to name two German examples, became world leaders in manufacturing and technology during the prewar era. However, two catastrophic conflicts not only set back the course of industrialization in Europe but ultimately hindered the organization of workers in most belligerent nations. There were significant strikes during the interwar years, such as the English General Strike of 1926 in Britain, but European trade unions generally collaborated with their governments when the lives of their nations hung in the balance. Discontent during the war years was generally channeled into other forms of protest like food riots. The Nazis successfully banned independent trade unions in 1933 and replaced them with a single National Socialist trade union, the Deutsche Arbeitsfront (German Labor Front), which suggests the greater importance of nationalism over class consciousness within Germany. After the Bolshevik Revolution in November 1917, trade unions became part of the Soviet state, ultimately hindering their ability to improve the lives of workers at state-owned factories.

Latin American countries had economies based primarily upon the export of crops and natural resources during this period, such as Brazilian coffee, Guatemalan bananas, and Venezuelan petroleum. Although food processing and textiles were the most important industries in the region before the 1930s, a spike in industrialization during that decade gave rise to new industries like chemicals, metals, and papermaking throughout the region. Workers were kept mostly in check during this era by political sys-

tems that did not give them enough freedom to organize themselves. More importantly, these economies remained overwhelmingly agricultural and with labor so cheap that businesses had little incentive to industrialize.

Domestic Work Forces during Wartime

The mobilization of entire economies for the war effort in the great conflagrations of the twentieth century, particularly during World War II, reflected the ability of states to harness the productivity of their respective workforces for the purpose of engaging in total war. The modern concept of total war, characterized by the mobilization of the entire national economy for the purpose of engaging in warfare, along with new weaponry capable of destroying vast amounts of property and life, made the civilian workforce vital to the war effort, as they were responsible for producing war matériel and munitions. Through various forms of government incentive, coercion, and persuasion, masses of both male and female workers put in endless hours at incredible toil and strain to keep their military forces equipped, sometimes amid aerial bombardments. The mass conscription of recruits, along with these new weapons, made governments in Europe and the United States capable of amassing gigantic forces of men and equipment to engage comparable forces on the opposing side.

During World War I (1914–1918) the gradual escalation of the conflict due to the stalemate on

the western front forced both the Allies and the Central Powers to mobilize their civilian workforces for their respective war economies. Imperial Germany mobilized its economy under the military dictatorship of Field Marshall Erich Ludendorff in 1916 after the civilian government under Kaiser Wilhelm II proved unable to cope with the economic strains of a two-front war. Compromises struck with the Socialist Party (SPD) quelled the potential for strikes and worker unrest. However, German war production of matériel soared, while food and consumer goods for civilians were in short supply. German workers had to cope with a poor diet and long shifts for poor pay. Both Britain and France attempted to mobilize their economies for total wartime production while hoping that ensured production and consumer goods would continue to help sustain morale among troops and civilians. Civilian governments set up near-dictatorial authority in terms of economic planning and the conduct of the war, both seen as crucial to the entire war effort. Workers on both sides were showered with patriotic and nationalistic propaganda and persuaded to invest much of their earnings in war bonds and loans. However, long hours, poor diet, and little to no access to consumer goods characterized the plight of most workers across Europe. The increasing centralization of national governments and the precedent for economic planning also characterized World War I's effect on economic mobilization for total war.

The Russian Empire suffered extreme hardships due to the strains of the war front and the workplace. Russian workers were forced into long hours with little to no incentive to work for what was deemed a lost cause. However, the Russian Revolution of 1917 raised the expectations of workers to create their own state. The Bolshevik coup in October 1917 finally led to the end of the war on the eastern front. However, the subsequent Russian Civil War (1917–1922) allowed the Bolsheviks to centralize their authority over the Russian economy through war communism. Taking a page from Ludendorff's total war economic mobilization, the Bolsheviks nationalized all industries within their sphere of control and, through incentive and coercion, mobilized Soviet industry for war and for the

A woman works in one of Moscow's factories in 1941. During World War II, millions of women worldwide became laborers to replace the men that were off fighting. (Library of Congress)

purposes of building socialism. Many Soviet workers, imbued with ideological fervor and motivated by the success of the Revolution, worked toward the victory over the whites (reactionary forces).

World War II (1937–1945) led to the total war mobilization of all the belligerents involved, now also including the United States and Japan. Total war mobilization during World War II, building on precedents from World War I, included more centralized political control over the war economy. Consumer goods and food were rationed for civilian use, and ration coupons and queues for goods become the norm. Countries subjected to aerial bombardment prepared their civilian workforces through drills and salvage work to ensure that production would be up and running as soon as possible. The infusion of women into the industrial workforce was ubiquitous in all countries except in

EXECUTIVE ORDER 8802

Executive Order 8802, also known as the Fair Employment Act, was signed into law by U.S. president Franklin D. Roosevelt on June 25, 1941. It was enacted partly in response to the demands of African American activists, such as A. Philip Randolph, who advocated legislation barring racial discrimination in war industries. Moreover, it was representative of the federal government's efforts to recognize the importance of African American labor to the war effort. It strictly prohibited racial discrimination in the national defense industry and was the first effort to promote equal opportunity and prohibit employment discrimination in the United States, particularly for African Americans. The order explicitly required federal agencies involved with war production to make sure that training and educational programs were administered without discrimination with respect to race, creed, and national origins. Furthermore, defense contracts were to be imbued with restrictions on discrimination. While race riots ensued in some industrial areas, African Americans gained opportunities previously denied. Executive Order 8802 was significant not only in that it recognized the importance of black labor in the United States but also in that total war mobilization created the opportunity for labor to exact demands from government in recognition of its importance to the war economy. Such concessions to labor were not available to workers in the authoritarian realms of the Axis and Soviet-controlled spheres.

—*Abraham O. Mendoza*

National Socialist Germany, which grew to rely increasingly on slave labor. In the United States, Britain, and the Soviet Union, war production ran at full capacity, churning out tanks, planes, artillery pieces, shells, and bullets and exceeding the capacity of the Axis Powers.

During World War II the civilian workforces of both the Allies and the Axis Powers were subjected to sacrifices, shortages, and—with the exception of the United States—the danger of aerial bombardments. Britain was able to produce an increasing amount of war matériel amid bombing attacks by the German Luftwaffe. Both Japan and Germany also managed to maintain adequate levels of war production amid aerial

bombing attacks by the Allies, but these decreased toward the end of the war as firebombing raids increased in intensity. Soviet war production, forced beyond the Ural Mountains by the German advance, increased its total output of tanks, planes, and artillery pieces through worker discipline and sacrifice and sometimes also through coercion. Soviet workers who did not comply with government demands faced time in forced-labor camps in Siberia, but many were nonetheless motivated by patriotism and vindictiveness toward the Germans. Both Germany and Japan, having conscripted most of their available manpower for the military, were increasingly forced to use slave labor from across their conquered territories in addition to children and the elderly. Workers in the Axis and the Soviet-controlled areas were subject to coercion and spying and could be arrested if seen engaging with suspected saboteurs. Long hours and a poor diet also took a toll on productivity, which was slowly placed on slave labor, particularly in German-controlled Europe and Japan's East Asian Co-Prosperity Sphere.

U.S. and British mobilization for war was a result of a coordinated effort between business and labor groups through government committees. War production and economic-resource allocation were coordinated centrally, ensuring the logistical efficiency of the entire war economy. Workers, both men and women, earned large wages and were provided incentives for higher output through overtime pay. African Americans played a large role in the civilian workforce, as unofficial racial hiring bans in war industries were lifted by governmental fiat and as demand outstripped labor supply. Many African Americans moved in droves to production centers in Seattle, Oakland, and New Jersey. Irish workers as well as many workers from the British empire flooded to England to work in Britain's factories as English men were conscripted to fight in Europe and North Africa. Many Allied laborers saved much of their earnings in war bonds and loans, which made a hefty profit for them in the postwar period. In contrast with the scarcity in the Axis and Soviet zones, both the United States and Britain were assured both guns and butter (both war and consumer goods), although Britain also received

many of its war goods through the U.S. Lend-Lease program, as did the Soviet Union.

Workplace Safety in the United States

In the United States it was not until the 1870s that the first state workplace safety laws were passed. Common law and laissez-faire economic policies in force throughout the nineteenth century put the burden of safety not on the employer but the worker. During the later part of the nineteenth century, a coalition of organized labor and social reformers successfully lobbied for two political reforms. First, the factory law movement persuaded several state governments to pass workplace safety laws requiring that dangerous machine parts, cogs, and belts be guarded. Massachusetts was the first of many states to pass a factory law in 1877. However, enforcement was usually plagued by small budgets, an insufficient number of inspectors, and employer opposition.

Second, many states repealed or reformed their employer liability laws, and juries began granting injured workers more liberal damage awards. Fearful that juries might continue granting larger awards, a coalition of major corporations lobbied for a system of workers compensation legislation that would make standardized but lower payments in lieu of a worker's right to sue. In 1908, Congress passed the first workers compensation law in the United States, but it only covered federal employees. Eleven states passed workers compensation laws in 1911, but it would be 1948 before all states had passed workers compensation statutes.

The limitations of dealing with workplace safety problems that were complex and national in scope at the state level were revealed by state

workers compensation plans. Many states weakened or omitted provisions deemed objectionable to the business community and the courts. As a result, the range of hazards covered, the types of workers covered, and the benefits given varied from state to state. Although the existence of many occupational diseases were known at the time, virtually all state laws excluded compensation for them. Office, agricultural, small business, nonprofit, and domestic workers were commonly excluded from most state plans, as were consultants and those engaged in interstate commerce. Although forty states and territories had enacted workers compensation laws by the end of 1917, 40 percent of workers were legally excluded.

The federal government took its first steps toward the regulation of workplace safety when it passed laws during the 1890s covering two of the most dangerous occupations: railroads and mining. In 1891, Congress passed its first coal mine safety law, which mandated ventilation standards and prohibited child labor under the age of twelve in the federal territories. However, it did not apply to the states, which generally had weaker standards.

Despite the fact that coal mining has been consistently ranked as one of the most hazardous jobs, it has usually taken a major mining disaster to get Congress to tighten up safety regulations. In December 1907, 600 miners were killed in two mine accidents that occurred within a two-week span, but lobbying by the Bituminous Coal Operators Association (BCOA) prevented Congress from establishing the U.S. Bureau of Mines until 1910. Even then, pressure from the BCOA precluded giving the bureau the power to regulate state mining conditions or even to enter mines. The coal operators' lobby was so effective that the federal government was not able to establish the authority to set and enforce safety standards and make black lung a compensable disease until the passage of the Coal Mine Health and Safety Act of 1969.

In 1910, the U.S. Bureau of Labor reported how the use of poisonous white phosphorus in the match industry caused phosphorus necrosis, or "phossy jaw," a deadly disease in which the jaw bone is eaten away. Known in Europe to be an occupational hazard as early as 1838, the use

of white phosphorus was banned throughout most of the industrialized world by 1910. Nevertheless, it was still widely used by the U.S. match industry because it was slightly cheaper than its nontoxic substitute. It took three years of pressure and President William Howard Taft's endorsement to convince Congress to act. In 1912, it placed an onerous tax on the export, import, or interstate shipment of matches containing the deadly substance.

One of the most common causes of railroad accidents during the late nineteenth century was the manually operated, link-and-pin system of coupling cars. According to conservative estimates, this practice accounted for 16 percent of workers killed and 36 percent of injuries in train-related accidents in 1893. Although the automatic coupler had been shown to be safe and effective by 1885, the American Railway Association (ARA) blocked the passage of federal legislation until 1893. Frustrated by congressional inaction, several states passed their own coupler bills. Alarmed at the prospect of having to comply with a variety of state coupler safety standards (some of which exceeded the ARA's proposals), the ARA reversed itself and lobbied Congress to impose uniform but loosely worded federal standards.

In 1893, Congress passed the Federal Safety Appliance Act, which required that trains engaged in interstate commerce be equipped with standardized automatic couplers, power brakes, grab irons, ladders, running boards, and hand brakes. Subsequently, the ARA twice persuaded Congress to extend the deadline for compliance with the law's two most important requirements: automatic couplers and power brakes. As a result, the law did not go into effect until 1900, but it was not until 1903 that Congress required at least half the cars of any train engaged in interstate commerce to be equipped with power brakes. Congress gave the Interstate Commerce Commission (ICC) the power to increase the required percentage, but it did not do so until 1910, when the minimum was raised to 85 percent.

In 1936, Congress took its first step toward the establishment of national safety standards by passing the Walsh-Healey Public Contracts Act. It mandated that any company doing more than \$10,000 worth of business with the federal gov-

ernment comply with the state safety standards where the work was being done. It also imposed child labor restrictions and mandated the eight-hour day and forty-hour week. However, enforcement of the Walsh-Healey Act was virtually nonexistent.

Business groups made two arguments against the act. First, the federal government was usurping a policy function that was best left to the states. But state regulation alone was unable to control the increasing variety and magnitude of industrial hazards that a technologically advanced economy, based on interstate commerce and giant corporations, produced. Moreover, a century of experience with state workplace safety standards demonstrated that they varied greatly in effectiveness and enforcement from state to state. Second, business interests maintained that workers, not employers, were the cause of most accidents. Business interests have espoused this view since the nineteenth century and have perpetuated it through the National Safety Council's "safety first" campaign that placed the primary burden for safety on the worker, not on management. The phrase "accident proneness" was first used to connote worker error in a 1919 study of industrial accidents and soon entered the popular lexicon as part of a public relations campaign to define the terms of the workplace safety debate.

Changing Societal and Cultural Roles for Women in the Workforce

Women became employed in a wide range of occupations in the first half of the twentieth century, primarily as a result of two world wars. Prior to the twentieth century, women were limited to a handful of occupations such as teaching, domestic work, and factory jobs. Many female workers were young and single or were widowed. Middle-class women worked in their family's shop or business performing a variety of tasks. Some women worked out of the home as seamstresses, laundresses, or nursemaids. Women also handled most household tasks, although their work was unpaid and not highly valued. In rural areas women produced much of the food. Women's education often focused on domestic skills. In Western nations women gradually gained educational opportunities, but few doors opened in the work world prior to World War I.

Laws supported the assumption that women could not or should not do certain types of work, but many women did work. About 20 percent of the American workforce was female in 1900, with about two-fifths employed in domestic work. Factory work ranked second, and as immigration increased during the next decade, many more women entered the workforce. In Great Britain prior to World War I, almost one-third of all women were employed in jobs that ranged from factory work to running boardinghouses. About 400,000 Mexican women were employed in factories and domestic work by 1900, and women were hired as clerks and office workers. Most Japanese women did not work outside the home, but the government encouraged young women from poor families to work in the textile mills for the good of the nation as the country industrialized. Women comprised about 60 percent of Japan's industrial workforce between 1894 and 1912, with many young women spinning and weaving silk and cotton. More than 80 percent of

► INTERVIEWS WITH WOMEN ABOUT WORK

In the 1930s Franklin Roosevelt's Federal Writers Project hired many workers to interview Americans about their lives, documenting a wide range of careers. Many women worked hard doing domestic work or in factories for little money. The Writers Project archives indicate that Mrs. B's experience was not unusual: "My first job up in Maine was washing dishes in a boarding house. I got my room and board, and \$8 a week. . . . Then I went to work in a paper bag factory; I operated a press that printed the bags—I used to feed the machine."

Margaret Hawley, a packinghouse worker, described conditions in the sausage department: "They have the old women hauling on the trucks. The young ones wouldn't do that heavy work. . . . I worked in there where they put up pressed ham in cans. I packed pressed ham that was full of worms. They know."

Henrietta C. Dozier, an architect who wondered "whether my life history will be of any interest," was far more unusual. "How did I happen to take up architecture—an unusual occupation for a woman? Well, even in my childhood I wanted to study architecture, and have drawn plans since I

was seven." She also said, "I have always had to compete with men, yes. In submitting designs, plans, bids, I have never asked any consideration at any time because I happened to be a woman; I put all my cards on the table in fair and honest competition, and ask only consideration on the same basis. For the most part I have been treated fairly." But in one instance, officials told her, "We are sorry, Miss Dozier, but we cannot give it to you because you are not a voter."

The comments of Mrs. Blount, a dressmaker, are also instructive: "Today, every woman who is eligible is expected to vote and is considered unpatriotic if she doesn't. . . . Now we have women evangelists, lawyers, doctors, nurses, congresswomen and others. Women now practically run the churches and other religious organizations. . . . And today we even have ladies flying." She exclaimed, "I wonder what next."

the silk and cotton workers were women when the industry peaked in the 1920s.

World War I's labor shortages allowed many women to assume jobs that had traditionally been held by men. In addition to rolling bandages and nursing the wounded, women worked in factories and other war-related industries, although wages were lower than men's, and child care was often unavailable. American women worked in textile mills making military uniforms and in the steel and oil industries. In Great Britain, the number of employed women increased by 22 percent, with the greatest increases occurring in the transport, banking, and munitions industries as well as in white-collar office and civil service positions. However, when the war was over, most women lost their jobs. Both British and American women workers resumed the more traditional occupations they had held in the prewar years, usually at much lower wages than men.

Women around the world held mostly traditional women's jobs in the postwar years. Even in Italy where a postwar government had removed most legal limits on women's employment, most females held physically demanding and low-paying jobs, often in agriculture and by the 1930s in industry and services. As the American economy prospered in the 1920s, more women became teachers and nurses, and law and medical schools established quotas for the number of women admitted.

With the Great Depression unemployment rose dramatically, and there were fewer opportunities for women to find work. Even so, some employers chose to employ females because of the lower wages, despite public hostility. In addition, many public and private sector institutions created antimarried women policies in an effort to keep men in jobs, with about three-fourths of school boards refusing to hire married women. European economies were depressed as early as the 1920s, and these nations also responded by discouraging women from working. Many European women did housecleaning, laundry, and other tasks that earned some money for their families, although they were not counted among the employed. In Italy where more than half of women workers were employed in agriculture and nearly a quarter

worked in factories in 1931, the government encouraged women to stay home, at least until World War II intervened. The Nazis in Germany attempted to relegate women to home and family, although many were employed as teachers, nurses, and domestic workers during the 1930s. With a worldwide depression, many Chinese women who had worked in silk factories and Japanese women who worked in silk and cotton mills lost their jobs.

In the Soviet Union after the Russian Revolution, better education permitted women to prepare for a range of new kinds of jobs. But as improved living conditions decreased necessity, less than 25 percent of women were employed by the late 1920s. Following the push to industrialize in the 1930s, laws that protected women workers were abolished so that more women could be employed in factories. Many Soviet women held jobs as scientists or academics by the mid-1930s, and the number of women physicians had increased more than 20 times to 42,000. But these jobs were not valued as highly as positions in the industrial sector.

Attitudes about women's workforce participation quickly changed as World War II began. Many women entered the workforce either out of patriotism or under governmental pressure to relieve labor shortages. In Nazi Germany women were needed to support the war effort both in the factories and on the farms. About half a million German women were employed in the defense industry during the war years, at first as clericals and telephone operators and then later in jobs that ranged from nursing to fire fighting to driving trucks. British women ages 18 to 50 were required to register for military duty, and single women between the ages of 20 and 30 were drafted from 1941 onward. By 1943 most married and single British women were serving in the military in a wide range of occupations or were working in industry, although salaries and compensation for war wounds were lower than those for men. By 1945 women comprised nearly half of the Soviet workforce. Many Soviet women also served in the military on active duty and saw combat. Six million American women joined the workforce, with about one-third employed in offices and one-third in heavy industry. Women comprised

40 percent of the workers in aircraft plants and 12 percent of those in shipyards. Women performed a host of nontraditional jobs ranging from drill press operators to truck drivers to gas station operators, usually earning higher salaries than they had made before. With the war's end, many women workers lost their jobs to the returning men and were forced back into traditional women's work, although women's labor force participation would continue to grow as the century progressed.

Forced Labor

Although slavery was officially abolished throughout most of the world in the nineteenth century, it survived through much of the twentieth century in the form of state-managed forced labor camps. The roots of the Soviet system of forced labor can be traced back to the tsarist period, which operated forced labor groups for punishment of criminals and forced exile to work areas for peasants. Almost immediately following the 1917 Russian Revolution and communist takeover, the Soviet government began the systematic imprisonment of political prisoners in concentration camps. The year 1929 marked a major turning point in the Soviet camp system, because Josef Stalin decided to implement forced labor in order to enhance the nation's economy and accelerate industrialization. The camps came under control of the Soviet secret police, and from there the whole Soviet system of forced labor commonly came to be called the Gulag. The term "Gulag" is an acronym from

➤ JAPANESE FORCED LABOR

Imperial Japan also utilized forced labor on a large scale during the twentieth century. During World War II, Japan supplemented shortages in its labor force by compelling prisoners of war (POWs) and civilians of captured territories into slavery. Although the numbers vary, estimates are that more than 140,000 Allied POWs, at least 1 million Chinese and Indonesians, and more than 600,000 Koreans were used for various slave-labor projects in Japan and throughout the Japanese Empire. Another infamous form of slavery was compulsion of thousands of Korean women and girls into forced prostitution. Commonly referred to as comfort women, they were, in most cases, sexual slaves.

Similar to German corporations, it was Japanese companies that asked for and chose to use slave labor during the war. Companies more than Mitsubishi and Nippon actually paid the Japanese military to use POWs in their factories and mines. In general, slave laborers were treated harshly and usually fed just enough to keep them alive. Estimates are that more than 30,000 Allied prisoners of war who were used for forced labor did not survive the conflict, of which at least 11,000 were American.

—Philip Flowers

the Russian words *Glavnoe Upravlenie Lagerei* (Main Camp Administration).

The Gulag became a massive state system of forced labor as political dissidents, aristocrats, ordinary criminals, army officers, prisoners of war, intellectuals, minorities, and common citizens were arrested and sent to serve sentences in the camps. Forced labor was used for a myriad of different activities such as food production, mining, construction projects, manufacturing, and timbering. One of the earliest and most infamous forced labor projects was the White Sea Canal. Stalin ordered this 141-mile (227-kilometer) canal, linking the White Sea and Baltic Sea, to be excavated by prison laborers using the most primitive of tools. Beginning work in 1931, more than 100,000 workers with hand tools completed the canal in less than two years, with the loss of more than 10,000 lives.

Conditions in the forced labor camps varied greatly depending on a camp's location, the type

Workers inside a Soviet forced labor camp in the Archangelsk region of Russia, between 1921 and 1941. (SV-Bilderdienst/The Image Works)

of prisoners, the type of work being done, and the overall economic and political situation of the time. For example, the outbreak of war, a wave of arrests, a nationwide famine, or other factors could have an adverse effect on the conditions of laborers. Despite these variances, overall the majority of forced laborers tended to lack necessary medical care and were underfed, underclothed, and overcrowded in primitive barracks. Most prisoners were subjected to long hours of physical labor. Punishments could be severe, and mistreatment by guards was not uncommon. Women especially faced the threat of rape or sexual exploitation.

From 1929 to Stalin's death in 1953, an estimated 18 million to 20 million people became forced laborers, with as many as 5 million in the Gulag system at any given time. At least another 6 million were forcibly resettled for work in remote areas that they were not permitted to leave. At the system's height, there were hundreds of camp complexes with thousands of individual subcamps throughout the Soviet Union and eastern Europe. There is no clear agreement regarding the number of deaths caused by the Soviet system of forced labor, but it certainly reached the millions. After Stalin's death the Gulag system began to be dismantled, and a mass release of prisoners began. However, forced labor did not disappear. Some camps were still used as prisons for criminals and political dissidents, and forced labor colonies still operated for decades.

Although the Nazis established their first concentration camp in 1933, the organized use of forced labor essentially began with the German invasion of Poland in 1939. The Nazis viewed the peoples of eastern Europe and the Soviet Union as a vast pool of available slave labor. Inmates in already-established concentration camps were used for labor, and the Nazis created additional labor camps and forced civilians, especially Jews, in newly occupied areas into labor battalions. Some labor camps fell under the administration of the Schutzstaffel (SS)—also in charge of the concentration camps and eventually the death camps—while the Deutsche Arbeitsfront (German Labor Front) operated others. German forced labor during the war essentially had two different goals: use captured populations to strengthen wartime production, and use labor as a means to kill Jews by working them to death. As the war began to turn against the Germans in 1942 and as labor shortages increased, slave labor became an even more integral part of the war economy.

The Nazis used forced labor for many different types of work, including agriculture, construction, and the armament industry. In addition, inmates were forced to perform various domestic duties within the individual camps for the guards, including cooking, washing, tailoring, playing music, and gardening. One of the especially brutal labor assignments was carrying huge rocks up the steps of the quarry at the Mauthausen camp. Thousands of women from eastern Europe and the Soviet Union became maids for German families and were usually treated little better than slaves.

Many private German companies made the voluntary decision to utilize slave labor during the war. This was a choice made not by Nazi officials but rather by corporate executives. Some of the largest companies that used forced laborers during the war included Siemens, BMW, I. G. Farben, Daimler-Benz, Krupp, and Messerschmitt. One of the most notorious examples of private use of slave labor was the immense petrochemical plant built near the huge Auschwitz camp complex. I. G. Farben invested the equivalent of millions of dollars in this plant, where productive labor was done by slaves who were either worked to death or sent to the gas chambers when they became unable to work.

Accurate numbers are difficult, but estimates are that at least 7 million people were forced into slavery by the Nazis. This number included civilians from occupied areas such as Poland, Italy, and the Soviet Union; prisoners of war; and Jews. Approximately half of the civilians pressed into labor by the Nazis were women. Although some laborers who were of those races that the Nazis regarded as higher received wages and benefits, those from what were considered lower races were paid little or nothing and were fed little. Jewish laborers were treated the worst, as work was seen as another means of annihilation. If conditions in the Soviet Gulags were terrible, the circumstances for many forced laborers

under the Germans were unimaginably worse. Unlike in the Soviet Union where forced laborers were serving a sentence, to the Nazis most laborers were viewed as little more than an expendable resource.

■ Introduction: Social Upheavals and Social Change

During the first half of the twentieth century, grassroots mobilization led to the dismantling of authoritarian power in the form of monarchies, dynasties, and colonial regimes, or the dismantling of oppressive practices while otherwise preserving the state. Social movements often involve a cultural dimension, which not only provides a basis of solidarity and collective identity among social movement participants, but in turn becomes part of the greater social transformation realized in the struggle for rights and resources. To trace a social movement historically is to disclose a template of the way inherited ideas, institutions, and social practices are challenged through cultural productions, actions, and the forging of new institutions. If successful, marginal ideas move from the periphery to the center.

Suffrage for women and minorities is one example of a social reform movement that slowly gathered momentum in the eighteenth and nineteenth centuries until what had once been “laughable” instigated major political, economic, and social changes in the early twentieth century for most of the industrial world. Often such reform efforts, always tied to ethical notions, had roots in religious thought and scripture—as was generally the case among leaders of the

nineteenth-century abolitionist movements in Europe and the Americas. In the twentieth century, the nonviolence and social vision espoused by Mahatma Gandhi also had clear underpinnings in religious thought. Other social movements stemmed from people’s spontaneous reactions to current events. The participants in the May Fourth Movement in China, for example, reacted in anger to news of the terms of the Paris Peace Conference near the end of World War I. From such amorphous beginnings came new leaders and the prompting to forge more lasting political changes.

Quit India was the polar opposite of an unorganized or spontaneous upheaval, instead involving many preexisting organizations, including labor unions and schools to choreograph the uprising. Yet, as with the May Fourth Movement, many of Quit India’s street-level participants were young people, willing to take risks to usher in change and end colonial domination. Although Gandhi’s strategy called for nonviolent tactics of protest and passive resistance, this mass upheaval also included violence and sabotage of property. Yet the movement’s participants were able to present their cause to the world as principled and just and to dislodge an occupying empire with no military maneuvering.

The entries that follow inspect the historical conditions under which social upheavals can lead to lasting social and political change.

—Josef Castañeda-Liles
and Fred Nadis

Nonviolent Resistance

Nonviolent resistance is a method employed by numerous movements for social or political change and can involve the use of picketing, boycotting, and pamphleteering as well as other methods of resistance devoid of physical violence. This particular form of resistance has been used throughout the modern era by feminists, socialists, labor, nationalists, and numerous marginalized groups. These movements have met with differing success depending on variations within economic structures, governmental systems, public opinion, and the particular movement's size and fervor.

In the Western world, nonviolent models have frequently been rooted in Christianity, ethical beliefs, and political analysis. Other world religions have also led to the development of nonviolent resistance movements based upon religious tenets such as with the Taoists, who believe in the concept of *wu wei* (effortless action). One of the most famous proponents of nonviolent action was Leo Tolstoy. Tolstoy was famous

for a number of novels, including his great 1894 manifesto on nonviolence, *The Kingdom of God Is within You*. This work was based on the Sermon on the Mount in which Jesus advocated with the phrase “turn the other cheek” nonviolence even when violence was inflicted upon a person. Tolstoy's text has provided leadership for nonviolent movements worldwide since its publication.

The most famous mass movement involving nonviolent resistance occurred in India in the 1920s when Mahatma Gandhi led the multi-phased Non-cooperative Movement against the British empire. Boycotts were first lodged against everything from imported British goods to schooling under a British imperialist educational system. In addition to this, Indians boycotted the visit of the Prince of Wales, Edward David Windsor, on November 17, 1921, by refusing to throw parades or offer celebrations; instead, Indians cleared the streets and closed the shutters on their windows. Other acts of civil disobedience, including the nonpayment of taxes, marked this era. This phase in the struggle for Indian independence came to an end in 1922 due to the eruption of violence surrounding the movement.

Gandhi led several successful acts of nonviolent resistance, a philosophy that he termed satyagraha that was the synthesis of the Sanskrit words for “truth” and “firmness” or “persuasion.” Gandhi increasingly became the face of the Non-cooperative Movement and led the Salt March of 1930. In protest of the British Salt Tax, Gandhi and many of his followers marched to Dandi where they threw thousands of bags of salt into the ocean. Gandhi also urged his fellow countrymen in other areas of India to violate the Salt Law, which outlawed the sale or production of salt by anyone but the British government. British officials deemed this movement as being very dangerous and quickly crushed it. Finally, Gandhi led the Quit India movement during 1942–1945, a movement that began in July 1942 when the Indian National Congress issued a document asking British forces to leave India. The document also warned that if their demands of independence were not met, a widespread civil disobedience movement would begin and engulf the entirety of India. The Indians were forced to

Indian proindependence leader Mahatma Gandhi and 78 of his followers march 240 miles to Dandi in March 1930 to protest the doubling of the salt tax by the British. (Library of Congress)

enact their plan, but this time they were successful, and the Quit India movement was followed by Indian Independence in 1947.

Most countries experiencing anti-imperialist struggles in the first half of the twentieth century attempted nonviolent resistance before turning to violence. Most of these movements, such as those in Ireland, Poland, and Finland, were marked by the boycotting of goods from the imperial powers or dominant ethnic group, the publication of banned newspapers or periodicals, the rejection of the nonnational language, and the proliferation of the traditional literature of the protesting ethnic group or minority.

Feminist movements have also relied on nonviolence to promote their agenda since the nineteenth century. Women's rights groups and suffragists across the globe often used public speeches, mass meetings, picketing, the disruption of political meetings, and hunger strikes throughout the early twentieth century. Many women died as a result of either hunger strikes or force feeding by the government when the hunger strikes gained too much publicity for suffragists.

Labor movements have also used nonviolent resistance, and the most famous of these movements that used strikes, boycotts, and civil disobedience was the People's Strike, better known as the Russian Revolution of 1905. The Russian Orthodox priest Georgi Gapon (1870–1906) drew up a petition for the people asking for better working conditions, higher wages, eight-hour workdays, and an end to the Russo-Japanese War (1904–1905). Gapon and a large number of workers marched to the palace of Tsar Nicholas II in order to present their petitions. However, the tsarist troops fired upon the workers as they approached the palace, killing 100 marchers and wounding 300 more. This event, which came to be called Bloody Sunday, was followed by massive strikes across Russia that included university students, middle-class doctors, lawyers, and other professionals. In October, the railway workers went on strike and paralyzed Russia.

Nicholas II and his chief minister, Sergei Witte, decided that the only way to end the nightmare was to offer some concessions to the people. The tsar created the Duma (a parliamentary body to ratify laws), granted free speech

➤ GEORGI GAPON (1870–1906)

Father Georgi Gapon was born to a peasant family in 1870. While training in the seminary for the Russian Orthodox priesthood, he was expelled due to his revolutionary ideas. He eventually went to St. Petersburg, where he worked among the poor and became acquainted with the cause of labor. As a consequence, Gapon developed a genuine sympathy for the workers and the many hardships they endured under industrialization. Although he was known for leading illegal trade unions and other workers' organizations from about 1903 onward, Gapon became famous following his role in the 1905 Russian Revolution in which he led a nonviolent protest of workers marching to the Winter Palace in order to present a petition to Tsar Nicholas II. The march ended in the massacre known as Bloody Sunday. Gapon escaped with the help of followers and decried the imperial actions from afar until his assassination in 1906. Despite his untimely death, Gapon's leadership combined with the general discontent of Russian society prior to the revolution led to a greater public outcry for reform. Nicholas II was forced to grant several reforms, the most important being the formation of the Duma, a governmental body of elected representatives.

—Christi McCallum

and assembly, and guaranteed the right to a trial before imprisonment. The 1905 Russian Revolution is considered a great success for nonviolent resistance, even though the tsar later revoked many of his newly granted concessions.

Numerous groups in the latter half of the twentieth century, including the civil rights organizations in the United States and antiapartheid movements in South Africa, used nonviolent methods similar to those that nationalists, socialists, and feminists had relied on during the first half of the twentieth century.

May Fourth Movement

The Chinese students' patriotic movement of 1919, better known as the May Fourth Movement, is a significant hallmark in the history of twentieth-century China. Greatly discontented with the terms of the Paris Peace Conference following World War I, Chinese university students provoked mass demonstrations in Beijing on May 4, 1919. The students hoped to restore externally China's sovereignty in Shandong Province and resist internally warlord govern-

ments. The origins and influences of the movement transcended the political dimension to include both immediate and far-reaching societal and cultural transformations. Such transformations continued to impact the development of China through the 1940s.

The May Fourth Movement stemmed from a number of internal and external factors. After China was opened by the West in the mid-nineteenth century, its agrarian economy was subjected to rapid changes prior to World War I. Foreign investment in China stimulated the expansion of its industrial, commercial, and financial enterprises, and these in turn contributed to the rise of industrialists, merchants, and urban workers within Chinese society. At the same time, the power of landlords in traditional agricultural enterprise diminished, while a new intelligentsia with knowledge of the modern West emerged in society. This intelligentsia was more sensitive to China's political development than other social groups within the empire.

Many of the intelligentsia had been educated in the West and upon their return to China responded to the political conditions both domestic and abroad, especially after 1915. The political changes in Europe, the rise of women's suffrage, and the policies of the Japanese government toward China provided favorable conditions for the outbreak of the movement. Some intellectuals used the media as a strategy to arouse the Chinese national consciousness in the hope of rejuvenating China. The journal *Xin qingnian* (*New Youth*) aimed to build a new China by destroying Confucian tradition, whereas *Xinchao* (*New Tide*) attempted to foster the effective intellectual and social development of modern China. Both journals, founded by Beijing University professors and students, adopted the vernacular style, which made the movement easily accessible to the masses.

When the news of the transfer of Shandong Province from Germany to Japan reached China in early May 1919, Beijing University students, inspired by their radical-minded professors through teaching and publications, provoked mass demonstrations, boycotts, and street lectures. With the support of the media, the movement rapidly spread to other groups, including industrialists, merchants, and urban workers. While the move-

► CAI YUANPEI (1868–1940)

Cai Yuanpei, protector of the Chinese students' patriotic movement of 1919, came from a mercantile family in Zhejiang Province of China.

Educated abroad, he was one of the radical-minded Chinese intellectuals of his time. In 1902 Cai founded two Patriotic Schools for boys and girls in Shanghai. He

was also involved in antidynastic revolutionary activities in 1900s' China. When Cai returned to China from abroad in 1916, he became chancellor of Beijing University, a known political center of student activism. Cai believed that university students should devote their efforts to learning and not to protest. However, when the May Fourth Movement broke out in May 1919, some students were imprisoned, and Cai launched a rescue campaign.

(Library of Congress)

—Yuen Ting Lee

ment was also embraced by students in other cities, Beijing University remained the center of activities. The immediate consequences of the movement were the refusal to sign the peace treaty with Germany and the punishment of the Chinese diplomats who made the secret agreement with Japan.

The unrest in May 1919 was not simply a student demonstration. It produced far-reaching consequences in the societal and cultural development of China in the later decades. Some Chinese women, for example, were awakened by the movement's leaders through the reading of their radical vernacular-style journals. The movement leaders' attack of Confucian ethics and the traditional family system accelerated the liberation of Chinese women. University coeducation was a case in point, as it broke down traditional gender barriers in the university setting. The vernacular style—the main focus of the Chinese literary revolution of the 1920s—helped to bridge the gap between the gentry and popular cultures. This literary revolution paved the way for the mass language movement in the 1930s. Another legacy of the May Fourth Movement was the formation of various social organizations, which were highly conducive to the mass demonstration movements in later years. As such, the consequences of the Chinese May Fourth Movement extended well beyond the university setting of Beijing, both in time and place.

Quit India Movement

The Quit India movement first gained momentum in April 1942 after the publication of Mahatma Gandhi's article "Foreign Soldiers in India."

> VICEROY LORD LINLITHGOW

Victor Linlithgow, Viceroy Lord Linlithgow, was appointed to the post of viceroy for India in 1936. His term ran until 1943 and was marked by the frustrations exposed by the Indian people during the 1942 Quit India movement. The first elections held under the 1935 Government of India Act, which Linlithgow had helped formulate, took place in 1937. Linlithgow was instrumental in convincing those elected to take their posts, despite reservations they may have had about provisions in the act. In 1939, however, with the outbreak of World War II, Linlithgow unilaterally declared war on Germany in the name of India. Waves of resignations from the government followed in protest. Despite the fact that Linlithgow's tenure as viceroy was the longest in the history of British India, his decision to declare war without consulting the Indian government proved to be a fundamental facet of the Quit India movement, which in turn helped expedite Linlithgow's resignation.

—Maryanne A. Rhett

Gandhi's article was in part a response to the Working Committee of the All-India Congress's call to end individual civil disobedience. Between April and August of that year, therefore, Gandhi and members of the committee met several times to try to come to an agreement on the objectives and goals of the Indian peoples. The continuation of World War II, British efforts to quell Indian cries for independence, and the progression of Japanese forces through South and Southeast Asia were collectively bringing the situation to a head. Finally proclaimed in August 1942 by the committee, the Quit India movement was marked by work stoppages, trade union, and student group-led demonstrations as well as guerrilla assaults on communications facilities and military installations. Arrest records of the era indicate that the great majority of those who were involved were from middle and upper castes and more often than not were students.

The Quit India movement's objectives were simple: the immediate withdrawal of the British imperial forces. Even as early as July 1942 British politicians in London were facing the reality that transferring power to the Indians following the

war had become inevitable. In a speech (often quoted since) delivered to the Congress on August 8, 1942, Gandhi gave the Indian people a simple mantra by which to live their lives: “‘Do or Die.’ We shall either free India or die in the attempt; we shall not live to see the perpetuation of our slavery.” Gandhi’s speech directed the actions of the coming campaign. Gandhi asked journalists to put down their pens, only returning to them when India gained its freedom. Gandhi did not ask soldiers to leave their posts but instead to refuse to obey any but just orders and never to open fire on their own people. Finally, of students and their professors, the most active component of the Quit India movement, Gandhi asked that they teach and lead the people down the path to independence.

Despite these calls for continued nonviolent action, the Quit India movement was marked by increased violence and revolutionary fervor, indicating a distinct shift away from Gandhian philosophy. The British reaction to Quit India was harsh. Viceroy Lord Linlithgow asserted that the Quit India campaign was the most serious uprising to face the Raj since the 1857 Rebellion. Instances of police shootings and even the destruction of whole villages were typical in the record between August 1942 and December 1943. Maintaining this level of violence to suppress Indian independence would be impossible, if even acceptable, in a postwar global structure.

Finally, while India moved in a decided direction away from British imperial presence, some found alliances with other imperial powers ad-

vantageous in expediting the process. Just as the Quit India movement was making headway, Subhash Chandra Bose’s Japanese-allied Indian National Army was also on the rise. Marching toward India, Bose hoped to attack the pro-British state with the aid of the Japanese in order to expedite the process of a British pullout. Conversely, Quit India meant not only the full removal of British power but also a subsequent declaration of Indian neutrality in the war in an attempt to stave off Japanese attacks on the subcontinent. Energies, Indian leaders felt, should be turned inward, focusing on the internal divisions and concerns that were causing violent rifts among the population.

In essence the Quit India movement was a success; Great Britain left India in 1947. From the standpoint of the Congress, however, the movement’s spontaneity denoted the Congress’s lack of control over the outcomes. The early arrests of the Congress leadership meant that they could not directly control nor benefit from the movement. What is more, the Congress, because of the denigration of its leaders, found itself playing political catch-up on the eve of independence and partition.

■ Introduction: Literature

The literature of the period from 1900 to 1945 reveals authors the world over grappling with the conflict between modernity and the vanishing of traditional lifeways. In Japan, authors such as Natsume Soseki contrasted characters nostalgic for the past with more “modern” types battling with a sense of ennui. What might be described as a literature of human rights also became common as authors gave voice to im-

poverished and exploited peoples. While some of this human rights literature was based in Marxism, often it offered an anticolonial or antiracist perspective, as could be seen in the literature of the Harlem Renaissance in the 1920s in the United States, the negritude movement among North African expatriates in France, and the *indigenismo* movement in Latin American countries. Such stirrings of identity literature often became

politicized, as racial hierarchies in places such as the United States and Europe were recognized as an extension of the colonial racial hierarchies imposed on much of the world. Political literature also could fall into the ultranationalistic camp of right-wing provocateurs, as in the profascist poetry of Marinetti or that of left-wing writers declaiming the values of communism and the needs of laborers to end their exploitation.

Proudly representing “modernity,” science fiction developed from its roots in the gothic novel as a sturdy and imaginative genre in this period. Writers such as H. G. Wells, C. S. Lewis, Olaf Stapledon, and Edgar Rice Burroughs offered high-brow fare and escapist fantasies that explored the impacts of new technologies, utopian possibilities, and travel through space and time. The genre gained a great boost through the development of fan-based magazines such as Hugo Gernsback’s pioneering *Amazing Stories*, which debuted in 1926. The dystopian science fiction novel also came of age in this period, particularly with works such as Yevgeny Zamyatin’s *We* (1920) and Aldous Huxley’s *Brave New World* (1932).

At the same time, this was an important period for aesthetic experimentation, as poets and novelists, influenced by revolutionary art movements such as cubism and dada and the insights of depth psychology, developed new techniques such as stream of consciousness, imagism in poetry, and the flat narrative voice common to Ernest Hemingway and detective writers such as Dashiell Hammett. The interwar period, marked by the Great Depression, also showed an efflorescence of a documentary aesthetic—particularly in the United States—as writers turned to understanding and documenting the plight of what Franklin Roosevelt had termed the “Forgotten Man.”

—Fred Nadis

Négritude

Négritude emerged as a literary and ideological movement in France during the 1930s. Led by self-identified “Negro-African” French-speaking writers, scholars, and activists, the movement sought to liberate the minds and bodies of the African diaspora from the insidiousness of French

colonial oppression. Négritude began with three unacquainted students—deferentially referred to as the *trois pères* (three fathers) of the movement—who met while studying in Paris in 1929: Aimé Césaire of Martinique, Léopold Sédar Senghor of Senegal, and Léon-Gontran Damas of French Guyana. These three men served as the artistic and philosophical architects of a cultural anti-imperialist campaign among African francophone intellectuals. Négritude addressed the particular historical, linguistic, and cultural complexities of being a Negro-African colonial subject of the French. In a general sense, the term “négritude” came to denote a rejection of Western imperialism and African assimilation. More specifically, the principal ambition of négritude was to facilitate the emancipation of Africa and the Caribbean by affirming the Negro-African identity, to condemn and ameliorate the historical symptoms of colonization and slavery, and to promote racial solidarity among the French colonies.

Heavily influenced by the early-twentieth-century writers and scholars of the New Negro Movement in the United States, the provocative writers of négritude scrutinized the prevailing Eurocentric notions of Africa, reasserting African sensibilities and promoting racial pride. New Negro poets, novelists, and essayists such as Langston Hughes, Jean Toomer, Countee Cullen, James Weldon Johnson, Sterling Brown, and Alain Locke served a fundamental role in fomenting the cultural nationalism of négritude’s leadership. And to this end, Claude McKay’s novel *Banjo* (1929), set in France, served as an archetype for the candid and politically charged analysis of the Negro-African condition. The New Negro’s cultural and political contestation of American race prejudice spurred négritude writers to equally challenge their own subordination.

The New Negro Movement was not the sole inspiration for the avant-garde authors and intellectuals of négritude. Also in Paris, a group of Martinique students strongly wedded to French surrealism and Marxist metaphysics equally sought a political arena to critique the longstanding inequalities of the French colonial system. In 1932 this cohort of activists published a single issue of *Légitime Défense* (*Self-Defense*), a journal devoted to political reformation. Although

➤ NEW NEGRO MOVEMENT

The New Negro Movement, commonly referred to as the Harlem Renaissance, was an artistic and intellectual movement that took place in the 1920s and 1930s. During this unprecedented time, the African American community challenged the aesthetic, social, and political restrictions of the previous era with new forms of cultural production as well as a new sense of self-determined racial pride. With the increasing labor demands of World War I, a large number of African Americans in the rural South migrated to the urban industrial cities of the North. This flood of African Americans, desperately searching for the economic opportunity and social freedom that was denied them by the prejudices of the South, secured more lucrative employment through the increased productivity of wartime industries. At the same time, this migrating population disseminated its rich culture and sensibilities and in doing so transformed American literature, art, music, theater, culture, and politics by ushering in an unparalleled era of African American achievement. The New Negro Movement cultivated a vast spectrum of cultural forms, including the philosophies of Alain Locke, W. E. B. Du Bois, and Marcus Garvey; the literature of Zora Neale Hurston, Jessie Fauset, Langston Hughes, and Claude McKay; the athletic achievements of Jesse Owens; the blues and jazz stylings of Louis Armstrong and Bessie Smith; and the artistic techniques of Aaron Douglas.

—Vida Robertson

this journal was short-lived, its ardent critique of French imperialism provided the framework for the *trois pères* to contemplate their own creative and philosophical perspectives.

Between 1929 and 1934, Césaire, Senghor, and Damas took progressive steps toward realizing their ambitions by collaborating with other like-minded student activists who also desired to continue the work initiated by the contributors of *Légitime Défense*. Consequently, in 1934 the *trois pères* inaugurated negritude with the founding and publishing of *L'Étudiant Noir* (*The Black Student*). *L'Étudiant Noir* was a literary journal devoted to the celebration of African cul-

tural expression and the creation of a Pan-African solidarity. The *trois pères*—unwilling to entirely subscribe to any particular political methodology as the guiding principle of their cultural renaissance—only incorporated the functional insights of Marxism, socialism, French surrealism, and the racial affirmation found in the New Negro Movement that directly advanced their cause. Thus, the impetus of the movement was not merely to reject Western values but, more importantly, to reassert patrimonial African sensibilities. By utilizing literature as an active force, *L'Étudiant Noir* redactors brought to light the systematic inequalities of racial prejudice and the desperate socioeconomic conditions that result from it.

Accordingly, in 1937 Léon-Gontron Damas was the first of the three founders to publish his work, which appeared in a book of poetry titled *Pigments*. In this collection Damas offers a fiery and unsympathetic critique of African absorption and Western superiority. His rhythmic, nostalgic, and witty verses received widespread acclaim. Contemporary literary scholars would later acknowledge this groundbreaking text as negritude's manifesto. Two years later, in 1939, Aimé Césaire published his much-celebrated collection *Cahier d'un Retour au Pays Natal* (*Notebook of a Return to My Native Land*). It is here among Césaire's vivid descriptions of life in Martinique and his biting yet sometimes humorous critiques of French tyranny that the term “negritude” is first introduced. *Notebook* is considered Césaire's masterpiece for its innovative use of language, imagery, and an unmistakably rebellious tone.

As for Léopold Sédar Senghor, his first compilation of poetry, *Chants d'Ombre* (*Songs from the Shadows*), was not published until 1945. This collection celebrates the ancestral heritage, communal strength, and vibrant culture of Senghor's beloved Senegal. Moved by a keen sense of alienation in Paris, Senghor evoked somber scenes of Africa and juxtaposed them with his castigation of France for its racist horrors. It is this intimate sense of devotion to Africa that led Senghor to resign in 1948 as Senegal's representative for the French Socialist Party in the French National Assembly and establish the Senegal Democratic Bloc. Over the next decade, Seng-

hor held several offices in the French legislature on behalf of Senegal. Unsurprisingly, in 1960 when France finally granted independence to its colonies, Senghor was elected the first president of the Republic of Senegal.

This historic struggle for self-awareness, dignity, and independence has had a far-reaching theoretical and literary effect around the world. The consciousness-raising black nationalism of negritude has cultivated such prominent works as Jacques Roumain's *Masters of the Dew* (1944); Léopold Senghor's *Anthology of New Black and Malagasy Poetry in French* (1947); Franz Fanon's *Black Skin, White Masks* (1952); Edward Glissant's *The Ripening* (1958); and the journal *Présence Africaine* (1947) edited by Léopold Senghor, Aimé Césaire, Albert Camus, Richard Wright, and Jean-Paul Sartre along with numerous others. Furthermore, negritude has played a significant role in fostering artistic and political progress throughout the world. Negritude's artists, activists, and intellectuals are directly responsible for the formation of the Congress of Negro Writers (1956), the African Union (1963), the World Festival of Negro Arts (1966), and the dynamic black nationalism of the Black Power and civil rights movements of the 1960s and 1970s. Undoubtedly, negritude's newly ordained field of Negro-African literature generated a nationalist discourse and a sense of racial unity that sought to ultimately dismantle the sinister grip of colonization, slavery, and racism on Africa's diaspora.

Japanese Literature as a Reflection of Conflict

The literature of early-twentieth-century Japan was shaped by a generation of writers who appeared after the nation's successful modernization in the previous century. Nineteenth-century Meiji intellectuals played an integral role in shaping and influencing the government-directed modernization, largely complete by 1895. By 1900, however, Japan's modern education system had produced intellectuals outside the Meiji elite. Lacking influential connections, most writers withdrew from society, nursing a sense of apathy toward sociopolitical affairs while exploring the nature of the individual in a modern Japan still burdened by medieval customs and social obligations.

Japan's intellectuals of the period 1900–1945 addressed the dilemma of life in a modern world by combining traditional beliefs and aesthetics with Western realism, individualism, and concepts of freedom and morality. Writers of this period may be loosely categorized into four groups: realists, naturalists, aestheticists, and Marxists. For most, their lives and writing reveal the difficulty of attaining social harmony for a modern man determined to live rationally in a society dominated by irrational tradition. Intellectuals attempted to portray life as realistically or truthfully as possible, the primary inspiration being their own experience. Unlike its Western literary inspiration, their writing avoided social criticism, instead becoming an introspective analysis of the self as a way to show that the crux of the conflict can be found within the individual, within human nature.

The realists, such as Mori Ogai (1862–1922) and Natsume Soseki (1867–1916), were a source of inspiration for later writers. Their subject was the elusiveness of finding harmony as a rational, moral individual exercising free will within the constraints of societal obligations. The careers of Ogai and Soseki reveal a growing frustration born of their own attempts to pursue a rational existence within the confines of a highly regulated modern Japanese sociopolitical system. The result was an air of resignation in the later works of Ogai (who was a career army medical

officer) and withdrawal from society by Soseki (who abandoned a position at Tokyo University in 1907 to live solely off his writing).

Following in the rational footsteps of Ogai and Soseki was the Shirakaba group, formed in 1910. The Shirakaba was composed of young elite men, such as Shiga Naoya (1883–1971), a fact that allowed them to challenge social norms with little fear of recrimination. They were idealists who posited that despite the vagaries of human nature, the individual has the power to harmonize oneself with nature and society, thereby attaining happiness and peace of mind. Because the Shirakaba saw themselves as moral exemplars whose abilities as artists benefited the rest of society, they wrote about their own lives to reveal to the world how one could attain harmony within society.

The rationalism of Ogai and the egoism of the Shirakaba were incorporated by another group, the aestheticists, such as Nagai Kafu (1879–1959), Tanizaki Jun'ichiro (1886–1965), Akutagawa Ryunosuke (1892–1927), and Kawabata Yasunari (1899–1972). Their original focus was the depiction of modern man's awareness as realistically, logically, and aesthetically pleasing as possible. Over time the aesthetic nature of their work overshadowed all else, drifting into fantasy and using the sensual or the exotic as subject matter best suited to the pursuit of aesthetic perfection. As their art left the bonds of reality, so the artists' lives left the bounds of society, withdrawing into their own world like the naturalists.

The naturalists were also inspired by Western realistic novels and liberal individualism as well as Japan's Buddhist tradition of detachment. The naturalists determined that truth could only be perceived within the self, so it was necessary to write from the perspective of the author. Thus was born a unique literary form called the I-novel, a form taken up by writers in other literary veins to become a singularly Japanese writing style. Authors such as Kunikida Doppo (1871–1908), Iwano Homei (1873–1920), and Dazai Osamu (1909–1948) developed the I-novel. The I-novel exemplifies the introspective, self-centered, and critical nature of the naturalist movement. I-novels almost never address societal problems, revealing the naturalists' depar-

ture from Western realism. The I-novel typically took the form of a confession, revealing the dark side of human nature. Many expressed guilt or shame for abandoning family and community in order to pursue a literary career. Most naturalists struggled financially, living lives of dissipation in a pathological rejection of the demands of Japan's modern bureaucratic society. Their novels lacked widespread popularity, as their writing was too dark and confusing for those inexperienced with the tenuous existence of the modern intellectual. Their lives, a spiral of self-destruction brought on by guilt and shame and heightened by alcohol, drugs, and diseases, became fodder for their self-recriminating novels.

The literary community was severely shaken with the rise of Marxist, also known as proletarian, literature in the 1920s. This genre was short-lived, as government suppression all but ended the production of Marxist works by 1935. Even though no significant works of literary merit were produced, Marxist literature had a lasting impact on Japanese literature for decades. The Marxist movement, riding a wave of victory following the Bolshevik Revolution in Russia, forced the literary community to take notice of Japan's social inequalities. The proletarian movement held some appeal for Japanese intellectuals in their shared view of the restrictive nature of society that denied individual freedom to live in accordance with one's ideals. Intellectuals from all walks of life were stirred by Marxist rational, scientific explanation of the causes of and practical solutions for society's ills. In addition, government suppression and the demands of Marxism's uncompromising and very Western idealism kept the movement on the fringe of Japanese society, mirroring the intellectual community. Marxist works, many produced by converted naturalists, borrowed the I-novel form to communicate the struggle faced by the dedicated individual, typically drawn from the author's personal experience although to express the author's opposition to, rather than escape from, modern society.

The brutal suppression of radical elements in Japan from 1928 stifled honest intellectual expression. Writers had few options: either cooperate with the imperialist agenda or remain silent. The 1930s' literature turned toward ro-

mantic portrayals of Japan's past or hopeless expressions of loss and guilt. With the advent of war in 1937, the state forced many intellectuals into "pen brigades," sending them into occupied territory under army command to promote imperialist policies. At home, severe censorship and rationing of paper and ink limited publication options. The struggle of modernity and individualism, as expressed by its writers, entered into hibernation, not fully to awaken until the end of the U.S. occupation in 1952.

Latin American Literature

During the first half of the twentieth century, Latin American intellectuals engaged in an extensive debate on the cultural identity of the subcontinent in general and their nations in particular. Until then, the elites, including the literary circles, were deeply influenced by a long-term vision of Latin America that was popularized by the Argentinian writer and politician Domingo Faustino Sarmiento (1811–1888) through his essay *Facundo* (1845). According to this author, the region was trapped in a fatal struggle between civilization and barbarism, that is, between modernizing forces such as urbanization and European culture and backward elements such as a hostile nature and primitive native peoples. In the minds of several Latin American intellectuals, the tragedy of World War I (1914–1918) revealed the limits of this idealization of Europe as the central plank of civilization and progress in a phase in which they were also experiencing dramatic contradictions and conflicts in their home countries. The search

for authenticity and cultural autonomy from the Old World became the dominant aspect of Latin American literature.

In Mexico, the revolution that broke out in 1910 stimulated an early renovation of literary production, which culminated in the novel *Los de abajo* (*The Underdogs*, 1915) by Mariano Azuela (1873–1952), who interpreted the revolution as a healthy reaction by popular classes and culture against a regime that imposed an authoritarian modernization. During the 1920s a new genre dawned: the *novela de la tierra* (telluric novel), which portrayed the sociopolitical problems of marginal areas of the subcontinent from a regionalist and popular perspective, suggesting a variety of interpretations and solutions. In *La vorágine* (*The Vortex*, 1924), for example, José Eustasio Rivera (1888–1928) denounced the lack of control by the Colombian state over the natural resources of its Amazonian interior. Ricardo Güiraldes (1886–1927) expressed in *Don Segundo Sombra* (1926) his nostalgic idealization of the Argentinian countryside, offering a reversal of Sarmiento's argument. The masterpiece of this genre, *Doña Bárbara* (1929) by Rómulo Gallegos (1884–1969), depicted a symbolic cross-generational conflict over land in the Venezuelan plains, where modern laws and education collided with a tradition of superstition and violence. Finally, *Vidas secas* (*Barren Lives*, 1938) by Graciliano Ramos (1892–1953) provided a pessimistic view of the tough existence of landless peasants in the droughty backlands of northeastern Brazil.

In the 1930s as a consequence of the global economic crisis that began in 1929, new radical trends developed on the scene of Latin American literary production, with a qualitative leap in textual refinement, range of themes, and political engagement. The most prominent literary movement of the period was *indigenismo*. In the regions where native peoples still constituted a considerable portion of the population such as Mesoamerica and the Andes, several authors published works in which the abuses and exploitation suffered by indigenous peoples became the main focus. This is the case of the collection of short stories titled *Leyendas de Guatemala* (*Legends of Guatemala*, 1930) by

Miguel Angel Asturias (1899–1974), who later obtained the Nobel Prize in Literature, and the novels of authors such as the Ecuadorian Jorge Icaza (1906–1978) and the Peruvians Ciro Alegría (1909–1967) and José María Arguedas (1911–1969). The writings of this last author in particular included an unprecedented use of a variety of Spanish deeply influenced in its vocabulary and syntax by Quechua, the main Andean native language. This tendency toward linguistic experimentation was shared by other Latin American intellectuals who were especially interested in giving voice to other humble and exploited segments of the population: a significant example is the phonetical transcription of dialectical expressions used by people of African descent that appeared in the collection of short stories titled *Los que se van* (*The Ones Who Go Away*, 1930) written by the three young Ecuadorians, Demetrio Aguilera Malta (1909–1982), Joaquín Gallegos Lara (1911–1947), and Enrique Gil Gilbert (1912–1975), and in the poems of Nicolás Guillén (1902–1989) from Cuba.

Some authors were deeply influenced by the European turmoil of the 1920s and 1930s and especially by the Spanish Civil War (1936–1939), which was directly experienced by two of the most prominent Latin American poets of the twentieth century, Peruvian Cesar Vallejo (1892–1938) and Nobel laureate Pablo Neruda (1904–1973) from Chile, as demonstrated by their respective collections *España, aparta de mí este cáliz* (*Spain Take This Cup from Me*, 1939) and *España en el corazón* (*Spain in My Heart*, 1937). In their rhymes, these two poets attempted to elaborate new forms of social and political criticism through an original combination of European socialism and a more in-depth comprehension of the peculiar Latin American geographical, ethnic, social, and economic profile. Such a task in the field of nonfiction was performed by the unorthodox Marxist philosopher José Carlos Mariátegui (1894–1930), who in his *Siete ensayos de interpretación de la realidad peruana* (*Seven Interpretive Essays on Peruvian Reality*, 1928) tried to harmonize pre-Columbian communitarianism with twentieth-century communism.

During the 1930s, the publication of essays on past and current affairs was particularly rich

in Latin America: indeed, in this period modern human sciences started to take root in the sub-continent. Some groundbreaking works in this field were *Radiografía de la pampa* (*X-Ray of the Pampa*, 1933) by Ezequiel Martínez Estrada (1895–1964), which explored the life and values of the Argentinian countrymen; *Casa-grande e senzala* (*The Masters and the Slaves*, 1933) by Gilberto Freyre, which is still the most influential study on slavery and racial relations in Brazil; and *Contrapunteo cubano del tabaco y del azúcar* (*Cuban Counterpoint: Tobacco and Sugar*, 1940) by Fernando Ortiz (1881–1969), who dedicated his intellectual life to a pioneering ethnographic analysis of African Cuban culture.

A novel attention to gender issues and a new wave of sophisticated female authors also characterized this period. Criticism toward the traditional role of women in primarily male chauvinist Latin American societies was expressed by a variety of writers who adopted a plurality of styles. The Chilean María Luisa Bombal (1910–1980), for example, published novels and short stories that were deeply influenced by European and North American surrealist and experimental authors such as James Joyce and William Faulkner. On the contrary, the Mexicans Nellie Campobello (1900–1986) and Rosario Castellanos (1925–1974) promoted women's emancipation within the boundaries of the Latin American regionalist genre.

Stream of Consciousness

Stream of consciousness is a narrative mode and literary technique that seeks to provide a sense of inner consciousness on the page, thereby offering access to the thoughts of a character in fiction. Readers are brought into contact with a character's point of view by way of an interior monologue. Stream of consciousness opens the imagined inner life of the character and reflects an associative process of thinking and feeling. This thought process is in the mind and may be addressed to the self. What is overheard in the mind may be sounds, rhythms, evocations of feeling, or visual observations as well as what is verbal. Stream of consciousness, as a technique, expresses the experimental tendencies of modernism. The flux of life reflected in stream of consciousness writing roughly corresponds with Henri Bergson's philosophy of *durée*, a sense of inner time rather than clock time. Stream of consciousness appears to let go of rational categories and external methods of characterization that were dominant in the nineteenth-century novel.

Dorothy Richardson's *Pilgrimage*, a 13-novel sequence that began with *Pointed Roofs* (1915), was the first book by an English-language writer to fully explore stream of consciousness, a writing style that the author called "interior monologues." Stream of consciousness became an important literary technique in the 1920s and can be found in the works of several prominent authors, including James Joyce, *Ulysses* (1922); Virginia Woolf, *Mrs. Dalloway* (1925) and *To the Lighthouse* (1927); and William Faulkner, *The Sound and the Fury* (1929). In addition, stream of consciousness can also be found in works by Marcel Proust, Samuel Beckett, and T. S. Eliot.

The term "stream of consciousness" derives from psychologist William James's 1892 essay in which he used the term to describe "adult consciousness itself." For James, stream of consciousness conveyed how states of mind occur in succession in personal consciousness, always changing and "sensibly continuous." James suggested that this was something more than a movement from sensation and simple ideas to complex ideas, as in John Locke's epistemology. Rather, for James this was one's "total concrete states of mind." Modernist writers began to uti-

WESTERN LITERATURE AND SCIENCE

In *Modern Fiction* (1925), Virginia Woolf wrote that the technique of stream of consciousness was a way to "come closer to life" and "to record the atoms as they fall upon the mind." She wrote that in the stream of consciousness in the fiction of James Joyce, he is "concerned at all costs to reveal the flickering of that inmost flame which flashes its messages through the brain." As French philosopher Henri Bergson observed, an interior sense of time may be distinguished from clock time. The work of Bergson and Einstein was absorbed by their contemporaries and influenced modernism. Bergson's time theories had some impact upon Virginia Woolf, James Joyce, Marcel Proust, Gertrude Stein, William Faulkner, and others. From free association in Freudian psychoanalysis and psychology to literature, an intuitive sense of fluid experience was increasingly present in the awareness of writers and thinkers in the early decades of the twentieth century.

—Robert McParland

lize the term to present thoughts and feelings as they occurred. An individual's images, recollections, and ideas were thus cast as flowing spontaneously in consciousness.

A key member of the expatriate arts community of Paris, the American writer Gertrude Stein's stream of consciousness writing and fascination with the visual arts styles of postimpressionism and cubism had considerable impact upon Ernest Hemingway, Ezra Pound, Sherwood Anderson, and other writers. Anderson called Stein's work "an entirely new recasting of life, in the city of words." Stein's unique prose presents thoughts as they occur in a continuous present. Stein's detractors called her *Tender Buttons* (1914) repetitive and illogical, but it was obvious to the modernists that her experiments were valuable.

In James Joyce's fiction, moments of epiphany or revelation are enhanced by this technique. Joyce's use of this method first becomes apparent in his novel *Portrait of the Artist as Young Man* (1916), in which the reader is invited into the thoughts of a Stephen Daedalus. Joyce's use of interior monologue is further developed in *Ulysses* (1922), and stream of consciousness emerges with

great force and creativity in Molly Bloom's monologue toward the end. Built upon wordplay, allusion, and stream of consciousness, the first word of James's *Finnegan's Wake* (1939), "riverrun," suggests the continuous flow of consciousness.

Marcel Proust's seven-volume *À la recherche du temps perdu* (*In Search of Lost Time*, also translated as *Remembrance of Things Past*), published serially from 1913 to 1927 in French, is told primarily in stream of consciousness fashion. In one famous episode, a sensation of the taste of a madeleine, a traditional small cake, draws up memories of the past that become simultaneous with the present. In these explorations of memory, at times stream of consciousness associations proceed for a dozen pages or more; there are incidental occurrences that trigger other images, sensations, and memories. This sequential pattern of free thought is characterized by long sentences, and time past is present in this first-person narration.

In Virginia Woolf's *Mrs. Dalloway* (1925) and in many of her other works, including *To the Lighthouse* (1927) and later experiments such as *The Waves* (1931), Woolf illuminates the inner impressions of her characters through stream of consciousness techniques. In *The Waves*, her earlier attempts at individual psychological portraits merge into a lyrical, somewhat dreamlike rendering of a group of six friends' linked memories and biographies. In her diaries, Woolf described it as not a novel but as "an abstract mystical eyeless book: a playpoem."

William Faulkner's *The Sound and the Fury* (1929) brings readers into the mental life of three members of the Compson family: Benjy, Quentin, and Jason. Each of their perspectives provides a retelling of the family's story around a central incident in the life of another family member, Caddy. Here, stream of consciousness intersects with the unity of action of a more traditional novel. This is a single story told several times as filtered through the consciousness of its characters. Action is revealed through their associations and memories. Readers perceive the associative processes in circling movements and proceed from a lack of clarity in the mind of Benjy, who is developmentally disabled; the brooding and sullen Quentin; and the fractured rationalist Jason. A

Nobel Prize winner, Faulkner's fiction in turn inspired many later novelists, including the Nobel Prize winners Gabriel Garcia Marquez of Colombia and Toni Morrison of the United States.

Imagism

Imagism is the literary movement, boosted by Ezra Pound in the autumn of 1912, which launched the careers of poets Richard Aldington and Hilda Doolittle (H. D.). Often characterized by scholars as rooted both in French philosophy (particularly the work of Bergson) and in the thought and poetry of T. E. Hulme and his circle, whom Pound came to know in London in 1908, imagism, according to Aldington in his memoir *Life for Life's Sake* (1941), was at least at first merely a label Pound used to advertise the poems Aldington and H. D. had written in Paris during the previous summer. Aldington writes that Pound was "so much worked up" by H. D.'s poems that, over tea in a bun shop in Kensington, he "informed us that we were imagists." Neither H. D. nor Aldington had ever heard of the word much less of the principles later used to define the movement. In fact, they had developed their ideas of modern poetry in part through Pound's influence and in part through their own rejection of Victorian sentimentality in favor of verse derived from their passion for Greek literature. Specifically, Aldington and H. D. had been reading the French symbolists, Villon, Verlaine, and Neo-Latin poetry, but had

been translating together short epigrams from *The Greek Anthology* and writing relatively short poems in free verse which captured the subjects, spirit, rhythms, and form of the Hellenic material.

The now famous bun-shop meeting was significant on several counts. Pound slashed away with his red pencil at H. D.'s poems and signed them "H. D. Imagiste," thereby giving Hilda Doolittle the initials which would serve as her pen name through her career. Pound's "naming" of H. D. was to be for her both a burden and a limitation with which she would struggle for years (was she a developing poet in her own right or merely Pound's protégée, merely an imagist?). Imagism soon became an important movement which gathered about it a circle of early modernist writers, both British and American, and formally heralded modernism in English poetry; it also forged trans-Atlantic links and made many writers (and readers) conscious of literature and its possibilities in an entirely new way.

Pound sent Aldington's and H. D.'s poems to Harriet Monroe at *Poetry: A Magazine of Verse* in Chicago. Acting as the journal's "foreign correspondent," Pound praised the work of his friends and advertised it over the months that followed by delineating its "rules." Aldington's work ("Choricos," "To a Greek Marble," and "Au Vieux Jardin") appeared in the November issue, in which Monroe described the "imagistes" as "a group of ardent Hellenists who are pursuing interesting experiments in *vers libres*." H.D.'s work ("Hermes of the Ways," "Epigram" and "Priapus") appeared in *Poetry* in January 1913. These poems as well as others by Pound himself and by their friends (Skipwith Cannell, John Cournos, John Gould Fletcher, F. S. Flint, Ford Madox Ford, D. H. Lawrence, Allen Upward, and William Carlos Williams, among others) soon appeared not only in *Poetry* but in *The New Free-woman* (soon to become *The Egoist*) in London. Amy Lowell also became part of the group.

Informally, these young poets had developed standards for the poetry they admired and wanted to write themselves. Aldington wrote in *Life for Life's Sake*, "We wanted clear outlines, directness, concision, unhackneyed verse." Pound rather cryptically formalized imagism's

"four principles" in a manifesto published in *Poetry* in March 1913:

1. Direct treatment of the "thing," whether subjective or objective.
2. To use absolutely no word that did not contribute to the presentation.
3. As regarding rhythm: to compose in sequence of the musical phrase, not in sequence of a metronome.
4. The "doctrine of the Image"—not for publication.

In order to advertise his new movement, Pound initiated a collection of work he entitled *Des Imagistes*, but by the time it appeared early in 1914, Pound was disillusioned with imagism and interested in developing a new movement he denominated vorticism. Aldington, H. D., and Amy Lowell pursued the idea of an annual volume of imagist verse and produced *Some Imagist Poets* in 1915, 1916, and 1917. Working together, they published their own work as well as poems by their friends, having decided that each writer would make his or her own selection and that all poets would be equally represented and appear in alphabetical order. Pound refused on this basis to be included. In his introduction to *Some Imagist Poets 1915*, Aldington amplified Pound's rules, stressing the use of "the language of common speech" and "the exact word" as well as "absolute freedom in the choice of subject." He explained the importance of presenting "an image," striving for poetry that was not necessarily visual but that "should render particulars exactly and not deal in vague generalities." The anthologies of this avant-garde movement managed to survive the conflict of personalities that led to Pound's defection, but they could not survive the war. With Aldington at the front, the project was abandoned in 1918, although Aldington would continue to draw explicitly on the continuing appeal of imagism in his two volumes of verse published just after his demobilization in 1919: *Images of War* and *Images of Desire*.

A decade later, when all of the original imagists had gone their separate ways, Aldington edited a final "imagist" collection, designed to

demonstrate the divergent artistic development since the war of all those writers who had once appeared under the movement's banner. With H. D.'s help, Aldington solicited an introduction from Ford Madox Ford and collected work that appeared in *Imagist Anthology 1930*. Lowell and Lawrence were both dead, and Pound once more refused to participate, but most of the others contributed at least one poem, if only as tribute to the movement which had encouraged their early work and given voice to an exciting experiment in early literary modernism.

Literature as a Voice of Protest in the United States

The period 1900 to 1945 was one of great ferment in literature in the United States, as modernism and its experimentation with multiple perspectives and voice was introduced while a reformist agenda was added to the tradition of the social realist novels that had begun earlier with naturalist writers such as Stephen Crane, Theodore Dreiser, and Frank Norris. Such novels of protest gained a great boost from the “muckraking” movement in journalism of the turn of the century as well as the public fascination with socialism and communism that accelerated during the difficult economic times of the Great Depression. During this period, African American

and women authors raised questions of social inequality, while others spoke against the hypocrisy of small-town life and sexual repression.

The muckraking movement in journalism generally accompanied the Progressive movement in U.S. politics in which industrialists, with their singlehanded pursuit of wealth and power, were no longer seen as social Darwinist heroes but instead were attacked for creating unstable social conditions and a potentially revolutionary underclass. The movement centered largely on McClure's magazine. McClure's staff writers, such as Lincoln Steffens and Ida Tarbell, specialized in exposés of political corruption, corporate malfeasance, and labor exploitation. Unlike the naturalist novelists that had preceded them, they presented a reform program. In a similar vein, the ardent socialist Upton Sinclair wrote dozens of novels that served as exposés including *The Jungle* (1906), which examined the meatpacking industry; *King Coal* (1917), which was set during a mining strike; *The Profits of Religion* (1918), which explored the clergy; *The Goose Step: A Study of American Education* (1923); and *Oil!* (1927).

In the early twentieth century, African American writers continued their protest of racism in all its facets. In 1903, W. E. B. Du Bois published his important tract *The Souls of Black Folk*. Du Bois described the tendency for African Americans to have a “double consciousness,” indicating a serious split between how they were perceived by the majority white society and their own experience of selfhood. He also argued that this split became part of the African American consciousness, as individuals living in a racist society tried to please both the white majority and the demands of their own race. A similar line of analysis with an added insistence on the need for self-definition was taken up in the anthology *The New Negro* (1925), which became a seminal document of the Harlem Renaissance of the 1920s and 1930s. Numerous African American writers associated with this movement, such as Zora Neal Hurston, Langston Hughes, and Jean Toomer, celebrated the black experience and the issue of the color line in poetry, novels, and plays.

With the extension of voting rights in 1920, women writers more easily became part of new

movements and the literary scene. In her novels, Edith Wharton chronicled the lives of the upper class and revealed how stultified and limited women's lives were in this milieu. At another extreme, Anzia Yezierska, then called the "sweatshop Cinderella," wrote of the lives of poor immigrant Jewish families in the United States and her own rebelliousness against her Old Country father's autocratic rule over the family, as in *The Bread Givers: A Struggle between a Father of the Old World and a Daughter of the New* (1925). Poets Hilda Doolittle (H.D.) and Gertrude Stein also brought a viewpoint welcomed in the avant-garde; to give one example, Doolittle's "Eurydice" retells the myth of Orpheus from the point of view of his doomed and angry wife. Edna St. Vincent Millay relied on older forms such as the sonnet to convey her passionate and nuanced sensibility.

Sexual permissiveness and greater openness concerning sex became prominent in the 1920s, and this was reflected in the era's films, magazine articles, and literature. Numerous novels were written that lambasted small-town life and its hypocrisy, denounced as "Puritanism" by journalists such as H. L. Mencken. Sherwood Anderson's *Winesburg, Ohio* (1919), detailed the stunted lives of the typical American small town. It included portraits of a possible child molester and another study of a young woman, driven to near madness by anomie, who runs naked in the rain. To directly offend the "Puritan," Joseph Moncure March's banned 1928 erotic poem "The Wild Party" offered a graphic narrative involving sex, drugs, and jazz at one imagined drunken party of the Flapper age. Novelist and memoirist Henry Miller, whose works were also banned in the United States, with his long rants and explicit descriptions of his sex life, attempted to portray the joy of living as a free spirit.

The Great Depression of the 1930s, which coincided with the end of Prohibition, curiously brought a new cultural sobriety. The party was over, and the Communist Party, with its fierce advocates, was in vogue, with many writers serving their apprentices while attending meetings of local John Reed clubs. Editor Mike Gold of the communist *New Masses* magazine insisted that realism was not enough; Marxism must be added.

➤ THE CURIOUS CASE OF JOHN DOS PASSOS

John Dos Passos (1896–1970) began as a literary hero of the radical Left but became a pariah in his later years. Dos Passos was a Harvard graduate, journalist, and novelist, and his work grafted modernist documentary techniques to a social realist agenda. His earliest novels offered a highly critical view of the military, based on his observations as a medical volunteer during World War I. Dos Passos was a radical but not a captive of the Left; although he contributed to *New Masses* magazine, often it was to debate the views of true believers and editor Mike Gold.

Dos Passos wrote numerous novels; his most famous work was *U.S.A.*, a trilogy that included *42nd Parallel* (1930), *1919* (1932), and *The Big Money* (1936). In its main theme, the novels explored the social ills of capitalism. His critique included organized labor and business elites, but he was particularly outraged by the rise and influence of the advertising and public relations industries. The novels follow the histories of men and women of all social classes.

While covering the Spanish Civil War, Dos Passos became outraged at the Soviet manipulation of the failed Republican cause, which included assassinations of Leftists who rejected the straight Stalinist party line. In the 1940s and 1950s, Dos Passos published novels that critiqued the Communist Party, the New Deal, and the labor movement. Leftists who continued to embrace communism during the Stalin years lambasted Dos Passos as a reactionary. Dos Passos ultimately identified himself with the radical Right and anticommunism.

—Fred Nadis

To Gold, the only worthwhile literature was proletarian literature, which would detail the lives and difficulties of the working class, the need for united action, and the guidance of the Communist Party. Numerous writers, whether communist or simply socially committed, answered the call. Some of the finer literary efforts included Jack Conroy's *The Disinherited* (1933), Robert Cantwell's *The Land of Plenty* (1934), and Clifford Odets's drama *Waiting for Lefty* (1935). Perhaps the best known of 1930s' social realist

➤ NO SAFETY IN THE JUNGLE

Jurgis Rudkus, the protagonist of Upton Sinclair's *The Jungle* (1905), is an optimistic Lithuanian immigrant who arrives in the United States with his youthful bride Ona and relatives. They find work in the immense Chicago slaughterhouses and meatpacking plants. The factory owners, however, pay only starvation wages to their predominantly immigrant workers, and the working conditions are inhuman, debilitating, and unsanitary. All develop health problems; the grandfather dies. Jurgis works in the fertilizer factory, the fertilizer being the ground-up remains of beef carcasses after the lard and tallow have been melted out of them and only the offal and the bones remain. Shoveling cadaver dust into bags, Jurgis soon gets a constant headache and has asthmatic problems. His wife works in the meat packery, where dirt, moldy rejected sausage, spoiled hams, rat droppings, and poisoned rats all go into the meat hoppers to be ground into sausage.

Sinclair's frequent use of narration in the second person directly addressed the readers and

drew them into his images, with remarkable power. Consequently, the descriptions of the methods of production in the meat factories were so shocking that *The Jungle* triggered a government investigation, the first book to do so since Richard Dana's *Two Years before the Mast* in 1841. Aided by the novel, Dr. Harvey Washington Wiley, chief of the Bureau of Chemistry and Soils of the U.S. Department of Agriculture, saw his demands finally enforced in the Pure Food and Drug Act of 1906.

Sinclair, however, had intended the food production to be an eye-catcher only. His focus was on the working conditions, and in the second half of the book the personal tragedy and recovery of Jurgis takes second rank to a socialist program. Critical reception also centered mainly around food production, even though Jack London had initially called *The Jungle* “the *Uncle Tom's Cabin* of wage-slavery.”

—Wolfgang Hochbruck

novels is John Steinbeck's *The Grapes of Wrath* (1939), which chronicled the difficulties of Oklahoma's “dust bowl refugees” when they arrived in California; their exploitation as farm laborers, their endurance, and the value of unions or government action to protect workers.

Literature as a Voice of Protest in Europe

The political and social instability that shook much of Europe in the first half of the twentieth century, in addition to two world wars and the

subsequent stirrings of the Cold War, created a wealth of literature protesting against the existing cultural and political status quo. A panorama of authors from 1900 to 1945 criticized contemporary society and politics, warning of both the values underlying bourgeois decadence and the radicalism of new political ideologies. Others proposed socialist utopias free of the constraints of the past and present. Writers such as Emile Zola, Thomas and Heinrich Mann, Erich Maria Remarque, Franz Kafka, H. G. Wells, Aldous Huxley, and George Orwell are representative of the literature that confronted reactionary Victorian values, capitalism, modern warfare, fascism, communism, and all forms of totalitarianism.

The intimate relationship between French politics and literature can be surmised in the French public's traditional adoration for public intellectuals, common since the days of Voltaire (1694–1778). Emile Zola's scathing works—which critiqued French politics, society, and economic structure—were read by an avid public. A great many of Zola's novels were aimed at the social injustices of French society and described the

plight of the less fortunate amid insurmountable odds. Zola's immense influence on Belle Epoque France was most notably felt in the Dreyfus Affair (1894–1906) when he penned articles such as “J'accuse” and was a fervent Dreyfusard (supporter of Alfred Dreyfus). Through his books, Zola also informed the French public about the virtues of socialism in his attacks on capitalist inequity, anti-Semitism, and reactionary conservatism, which were all prevalent in the French Third Republic.

Late imperial Germany also produced a bevy of writers who were critical of German society and its ubiquitous class divisions, the rampant militarism and jingoism, widespread anti-Semitism, and the decaying bourgeois value system. The Mann brothers, Thomas and Heinrich, produced a multitude of novels that critiqued late imperial Germany. Thomas Mann's first novel, *Buddenbrooks: The Decline of a Family* (1901), traced the decline of a well-to-do merchant family over four generations, sharply criticizing the decaying values of the German middle class. His brother Heinrich typically wrote about social issues and scathingly critiqued the authoritarian and militaristic elements developing in the Weimar Republic. His novel *Der Untertan (Man of Straw)*, published in 1918, depicted the life of Dietrich Hessling, a typical German nationalist from prewar Germany who embraced the reactionary values of militarism, anti-Semitism, and chauvinism while despising socialists, Jews, and women. Heinrich Mann uses the character of Dietrich to illustrate the vacuous and empty nature of German bourgeois society, which tried to emulate German aristocratic values.

The onset of World War I destroyed the pre-existing social structure of Belle Epoque Europe while sending millions of men to the trenches and to their untimely deaths. The social and economic dislocations of war for both soldiers and civilians and the mounting death tolls at the front severely affected the public's views of the traditional values advocated by their elders. The so-called front generation, which saw their fellow soldiers die in droves in machine-gun fire or shelling attacks, was deeply shaped by their experiences during the war. Erich Maria Remarque's novel *All Quiet on the Western*

➤ GEORGE ORWELL—LITERATURE AS POLITICAL COMMENTARY

George Orwell (1903–1950), the pseudonym of Eric Blair, was a British author who penned a multitude of fiction and nonfiction works that criticized imperialism, capitalism, authoritarianism, and Stalinism, reflecting the many political concerns of the first half of the twentieth century. His older works, such as *Burmese Days* (1934), *The Road to Wigan Pier* (1937), and *Homage to Catalonia* (1938), written in his days as a journalist, illustrate his own experiences and disenchantments with British imperialism, social inequality, and encroaching Soviet communism. However, Orwell's most notable works include *Animal Farm* (1945) and *1984* (1949), which were scathing critiques of totalitarian societies and their characteristic police states. Despite his socialist leanings, he exposed the coercive policies that such states imposed under the pretense of egalitarianism or in response to real or imagined external threats. Much like H. G. Wells and Aldous Huxley, Orwell illustrated the flaws of current European ideological movements in his two major dystopian studies. In the eyes of Cold Warriors and conservatives in the West, Orwell's critique of Stalinism in *Animal Farm* and in *1984* established Orwell, despite his advocacy of socialism, as a prophet decrying the Soviet Union and global communism.

—Abraham O. Mendoza

Front, published in 1929, encapsulates the experience of World War I from its depictions of ubiquitous slaughter in the trenches to the miseries of the German home front. Remarque's novel depicted the experiences of the common soldier not as a heroic warrior of Victorian lore but as a mere boy duped by nationalists and politicians to engage in a senseless slaughter that neither side was able to bring to an adequate conclusion.

The interwar period (1919–1933) also stirred many European authors to expose the ideology and goals of totalitarian systems (such as fascism, National Socialism, and communism) as threats to human liberty. Jewish-Bohemian author Franz Kafka wrote about individuals struggling within tightly controlled bureaucratic

worlds in his novels *The Metamorphosis* (1915), *The Trial* (1925), and *The Castle* (1926). A recurring theme in Kafka's surreal narratives is the helplessness of individuals against external forces beyond their control in the form of governments, political movements, and mass society. Kafka's work elucidates the growing power of governments at the expense of the rights of the individual. Many of these literary themes also characterized elements in Weimar Germany's Expressionist theater, particularly that of Bertolt Brecht. Similar themes also inflected the research of the Frankfurt School with its noted Marxist scholars Theodor Adorno, Herbert Marcuse, and Walter Benjamin.

British authors H. G. Wells, Aldous Huxley, and George Orwell also fervently attacked the existing social order, the development of modernity, and the dangers of the emergent ideological movements throughout Europe. H. G. Wells's novels, such as *The Time Machine* (1895) and *The Invisible Man* (1897), were pointed critiques of capitalism, modernity, technology, and humankind's destructive capacity. His later works, such as *The Shape of Things to Come* (1933), warns about impending world war and the creation of a world state under a benign dictatorship, thereby espousing his socialist views given the social chaos prevalent in the 1930s. Many of Wells's works were deemed prophetic of events to come, such as World War I and World War II, National Socialism, and the rise of communism in the Soviet Union. His fellow Englishman, Aldous Huxley, also ventured to critique the West in his own dystopian (or dysfunctional utopian) novel *Brave New World* (1932) in which the future is characterized by predetermined genetically categorized social classes bound to specific societal roles. In this dystopian future, pharmaceutical drugs and escapist entertainment (the so-called feelies) are in common use as a way to cope with the dreariness of day-to-day life. To Wells's critique, Huxley added a prescient vision of the dangers of eugenics (or genetic engineering) and mindless consumerism.

Literature as a Vehicle for Nationalist Movements

In the first half of the twentieth century, nationalist discourse in world literature became widespread, albeit for varying ideological purposes. After World War I, Leftist literature that critiqued the role of nationalism in creating the war became popular among segments of the war-weary public in the West. Yet in interwar Europe, advocates of fanatical nationalism, such as fascists and National Socialists, popularized a more pronounced nationalist literature. As these movements saw themselves as a vanguard against the forces of revolution (particularly from the Soviet Union) stemming from the Left and as a replacement for the weakened liberal democratic systems inherited from the prewar period, much of their literature celebrated war, racial superiority (with anti-Semitic overtones), and the seizure of power as a means of gaining political authority. Simultaneously, across much of the non-Western colonized world under the control of the Great Powers of Europe, nationalist literature that focused on the plight of indigenous people against their imperial overlords imbued the emergent struggle against European imperialism with a sense of greater purpose.

Interwar Italy entered a dire political and economic situation following the cessation of hostilities (1918) and the signing of the various surrender treaties (1919). Nationalists in Italy felt slighted by the fact that they had acquired minimal amounts of territory at the expense of the former Habsburg empire in spite of the Italian war losses. The Italian Gabriele D'Annunzio and 2,000 troops seized the city of Fiume on the Adriatic coast from Allied occupied forces, claiming it for Italy. D'Annunzio was a notable scholar and poet as well as a fervent Italian nationalist. Following the Fiume episode, D'Annunzio retired and spent his latter years writing and campaigning for nation-

alist causes. While D'Annunzio had a strong influence on the fascist ideology of Benito Mussolini, he never became directly involved in government politics in Italy. Other writers, such as Enrico Corradini, Alfredo Oriani, Giosue Carducci, and Filippo T. Marinetti, much like D'Annunzio, also wrote nationalist tracts exalting violence and war as positive forces for national regeneration. Many of these writers' written works had preceded the war and had fostered themes celebrating Italy's Roman heritage and the excellence of the Italian race. Among these writers, the Futurist Marinetti advocated fascism as the best way for the Italian people to restore their former artistic and cultural glory. Much of this literature was absorbed by young Italians immersed in the ideological fervor of the postwar era.

German high culture in its literary forms, mostly a reserve of the political Left during the postwar Weimar period, stood in opposition to the nationalist desires of the emergent Radical Right, particularly that embraced by the National Socialists. However, National Socialists did procure the services of many mediocre nationalist writers to popularize their racist and anti-Semitic ideology to the masses through literature, particularly Adolf Hitler's own autobiography *Mein Kampf* (*My Struggle*), published in 1925 and 1926 in two volumes. Similar to intellectuals and their involvement in Italian fascism, some German authors and poets did advocate National Socialism. Noted philosopher Martin Heidegger in particular remains notorious, given his level of involvement in the party and in intellectual discussions regarding the virtues of Nazism. However, it was not until Hitler's ascension to power in 1933 that liberal and Leftist literature was promptly abolished through censorship and book burnings, particularly those of Jewish writers. The theme of national regeneration through war and struggle was prevalent in much of this literature and, while of low literary quality, was still readily absorbed and accepted by many Germans.

Nationalist literature across the colonized world had preceded World War I but was embraced only by the small literate elite with access to education. The British, French, Dutch, Portuguese, Spanish, Italian, and German co-

➤ HEIDEGGER AND HITLER—NATIONAL SOCIALISM AND INTELLECTUALS

As the purge of German Jews from academia gathered steam after Hitler's ascension to power in 1933, many in German academia refused to abide by the Nazis' anti-intellectual ideology and censorship. However, others gladly accepted the change and embraced the political tenets of National Socialism in their respective fields, such as law, medicine, history, and philosophy. Among the most famous German intellectuals to accept and even advocate National Socialism was the influential philosopher Martin Heidegger. He served as rector of the University of Freiburg in 1933, a few months after Hitler's rise to power, for nearly a year. Furthermore, in many of his works written during the period, Heidegger made references to National Socialism, most of them in a positive light. Later in life, Heidegger denied that his involvement with National Socialism was ever sincere, commenting that he was only attempting to preserve intellectual freedom in universities as best he could. However, given his support for various Nazi policies and some of their ideological tenets in his work, it remains uncertain that this was in fact the case.

—Abraham O. Mendoza

lonial empires held sway over huge swaths of Africa, Asia, and Oceania. Intellectuals such as Indian Nationalist Mahatma Gandhi had already written numerous articles criticizing British imperialism and the position of Indians in South Africa in the early 1900s, already showing his distaste for British colonialism. World War I had shattered the illusion of Western invincibility, and many colonized elites had seen the chaos and disorder in Europe in the midst of the war, giving further strength to arguments against European colonialism and in favor of national independence in world regions such as India and the Middle East. As many of these men (and they were mostly men) had fought for the colonial motherland, many of them expected some type of autonomy or self-determination (a notion popularized by President Woodrow Wilson). When these expectations were not met, critics of imperialism, such as Indians Mahatma Gandhi and Jawaharlal Nehru and Vietnamese Ho Chi Mihn,

emerged as nationalists and authors of colonial nationalist literature.

Marxism and Pan-Africanism also emerged as stimuli to anticolonialist literature. The success of the Russian Revolution and the creation of the world's first workers' state had a significant influence on colonial nationalist literature, as some authors professed admiration for the Soviet experiment as a successful departure from European imperialism. During the 1920s and 1930s African American writers of the Harlem Renaissance wrote not only of the plight of blacks in the United States but also of the subjection of African blacks to European colonialism, thereby creating a Pan-African nationalist literature. Much of this nationalist literature advocated working against colonial authorities, either through violence or nonviolence, and also celebrated the history of the colonized peoples before the arrival of the Europeans. While couched in the language of the European Enlightenment, encouraging equality and political liberty, much

of this literature also developed a unique sense of national purpose identified with the colonized country in question and its history. Unlike the nationalist literature in Europe, which during the interwar period advocated racism, violence, and the colonization of "inferior" foreign peoples, much of the literature in the colonized world merely advocated breaking away from European authority and setting up autonomous or independent states.

■ Introduction: Visual Arts

In the field of visual arts, that is, painting, sculpture, and architecture, an enormous transformation occurred during the first half of the twentieth century. The classical forms and the artistic vocabulary of the Renaissance classicism lost its predominance. The artists whom we call "modern" tried to develop a new artistic vocabulary, mostly in opposition to the curricula prescribed by well-established academies of arts, such as the Ecole de Beaux Arts in Paris. The search for new artistic forms moved in various directions. Some artists sought inspiration in African tribal art; others saw raw industrial forms and materials as beautiful. Other groups, such as the surrealists, believed that true art comes from the untrained and the unconscious mind. What all these movement had in common was their challenge to the classical academic arts. They saw themselves as the avant-garde, soldiers on the front line of the struggle

between the old controlled world of the academic neoclassicism and the new exciting world of fast-paced improvisation. The whole movement is called modernism and is represented by names such as Pablo Picasso, Georges Braque, and Walter Gropius. These modern artists undertook and accomplished a successful revolution in the arts that threw out the established academic curriculum based on human figure, perspective, and classical styles.

However, after World War II the avant-garde rebels themselves became the establishment. The majority of artists mentioned in this topic are now veritable household names. Yet in the first half of the twentieth century, they were still young and trying to make a name for themselves and win large commissions. Once they acquired their niches in the growing industries of visual media, they quickly created their own unified sense of style, the so-called international modernism.

The career of Le Corbusier (Charles-Édouard Jeanneret-Gris), one of the most prominent modern architects, can serve as an illustration. Between the two world wars, Le Corbusier was not an unknown architect, but the buildings that he created were mostly private villas in Parisian suburbs. He still did not yet complete his great commissions that brought him fame and prestige in the artistic world. After World War II, Le Corbusier and his followers in the International Congress of Modern Architecture would receive commission to design not just private villas but also whole cities, from Baghdad to Brasilia, and important landmark buildings such as the new United Nations headquarters in New York.

Modernists' dislike for the European Classical tradition opened the door to a revived interest in folk art—and at this time we are talking about the art of the colonized world. It was the art that the academic neoclassical tradition often characterized as “primitive.” The modernists therefore loved the “primitive.” An African tribal mask was considered as beautiful as a classical Greek sculpture, and this caused consternation among the largely middle-class bourgeois audience. Cubists especially drew their inspiration from African art. Native American art found its way to elite art galleries of major industrial cities, especially as this tradition was mediated for the Western audience by the work of Mexican painters Diego Rivera and Frida Kahlo. The Modernists wished to change the prevailing tastes, and by the end of World War II they achieved this.

Furthermore, the modernists also wanted to change society in general. It is interesting that most modernist artists, with some notable exceptions, were on the left of the political spectrum. Bauhaus, one of the most influential schools of modern art, aimed at changing the bourgeois character of the relationship between the patron and the artist. Modernists wanted to produce art for the average mass consumer, not for a lonely and wealthy bourgeois connoisseur. Modern architecture was even more ambitious; its practitioners wanted to change, or even eliminate, prevailing class differences in modern industrial societies. To us today these ideas might seem naive, but at the time it was an essential part of the modernist revolution in arts.

Nothing exemplified this failed ambition as does the career of the architect Mies van der Rohe. In 1926 he designed an avant-garde monument to Karl Liebknecht and Rosa Luxemburg, leaders of the failed communist revolution in Germany. But after World War II, van der Rohe's glass and steel buildings became a widely recognized symbol of the largest and most powerful corporations in the world, such as IBM, Seagram, and American Life.

African Visual Arts

African art in the early twentieth century remained largely traditional despite the incursions of European colonial powers and ensuing cultural upheaval. Wood carving was almost ubiquitous south of the Sahara, as shown in the photographic evidence gathered by the colonial masters in their documentation of this art form. Many of the wood sculptures before that era could not survive the termites and decay that resulted from the region's climate. Ethnographic and anthropological studies of ancient Africa relied on archaeological finds that were in nonperishable media, such as metal and stone.

The visual arts of this period were referred to as tribal art. The traditional carvers of wood, ivory, and stone as well as the metal casters and potters worked within the context of the tribal system, expressing the religious and artistic values of their communities. The wood that carvers chose varied according to the type of work or the function that the finished object would perform. Carvers chose wood for a variety of reasons, including its hardness or softness, because it came from a certain tree with sacred affinities, or because it allowed for a particular kind of finish. For example, among the Kalabari, located in the Niger Delta, special woods are associated with heroes, the dead, and the water spirits. Among the Dogons, found in the central plateau region of Mali, the termite-resistant hardwood is chosen for masks that are supposed to last, such as for effigies of ancestors, whereas if the sculpture is an ephemeral piece, it may be made with

➤ PARADIGM SHIFT IN AFRICAN ART

During the twentieth century, most African countries at one time or another witnessed a shift in the arts from magic and ceremonial purposes to images created for aesthetic purposes. This shift occurred at very different moments in different countries, representing a long process in which traditions and modernity interacted to set a new paradigm in the arts of the continent. The period of shift to modern art in Africa, influenced as it was by the Western arts, paradoxically coincided with the era in which the Cubists first found inspiration in classical African sculptures for a sweeping radicalization of Western artistic styles. During this same period Africans began to take up easel painting, to paint portraits and scenery in the naturalistic style, and to shift away from art primarily dedicated to ritual ceremonies and magic practice toward a more purely aesthetic orientation.

This newly imbibed naturalistic paradigm in Africa quieted critics of African art who opined that Africans were too primitive to produce fine arts. First among Africans to tread this new paradigm was Aina Onabolu from Nigeria. He ordered his professional art materials from London, introduced art lessons in the Schools of Lagos, and initiated the training of artists in Nigeria.

—*Tolulope Lawrence Akinbogun*

soft wood. Among the Bangwa in western Cameroon, the seasonal hardwoods are favored by carvers because they last longer.

African sculptures in wood, widespread in sub-Saharan Africa, are the most common African art pieces in museums and private collections. It was through wood carvings that African art was initially recognized outside the continent. Extant African wood sculptures are rarely older than two centuries, with the exceptions of some of the figures that the Dogon ascribed to the Tellem and a Yoruba Ifa divination tray. The Dogon Tellem figures were dated to the twelfth century CE, while the Yoruba Ifa divination tray was dated to the first half of the seventeenth century. Most African wood sculptures, however, date from the eighteenth century to the present. By 1900 the West developed ethnographic interests in traditional

African art, and a handful of scholars started field-work gathering data for books on African art.

Wood sculpture of the early twentieth century allowed for the incorporation of other media by sculptors or those who use the objects. These other media were seeds, grains, pieces of leather and cloth, feathers, cowrie shells, metal objects, beads, small bells, animal teeth, and horns. With these media, varieties of dance masks and ritual figures were produced. Also, items such as assorted utensils, neck rests, stools, thrones, quivers, loom pulleys, beakers, boxes, and drums were made with wood and other media. Some tribes in Africa such as the Yoruba (Nigeria), Edo (Benin), and Bamileke (Cameroon) fashioned various decorative objects, including armlets, bowls, and boxes, from elephant tusks.

Some of the African sculptures from this era were influenced by European themes. Before the nineteenth century, Portuguese merchants commissioned African craftsmen to make items such as salt cellars, hunting horns, spoons, and forks. Some of the ivories were carved by Benin sculptors, although most are in a style similar to the *nomoli* figures of Sierra Leone. It was argued that the first artworks brought back to Europe from Africa were the ivories carved by Africans based on European models.

The Benin bronze works flourished vibrantly up to the British conquest of the city in the late nineteenth century. Benin artistic grandeur produced a royal art consisting of bronze figures, bronze plaques, state swords, carved ivory tusks, masks, and bells. Benin's products also included the paraphernalia of kings and chiefs consisting of coral beads, royal crowns, and coronets displayed at important ceremonies of a new *oba* (ruler) and other state events.

Pottery was a common craft that vigorously entrenched itself into the social, economic, and religious life of the peoples of sub-Saharan Africa up to the middle of the twentieth century. Through pottery, the ethnographic study of the people became unambiguous. The traditional African system of class based upon age continued to manifest itself in the visual arts of the early twentieth century. For example, the Sen- ufo potters in Cote d'Ivoire made pottery that

represented the form, organization, and operation of the Senufo age-class structure.

In the early twentieth century some Western artists were tiring of the Western naturalistic style of art that had been introduced during the Renaissance, and these artists began searching for new styles. The experiments of these turn-of-the-century modernists culminated in movements such as impressionism, fauvism, cubism, and pointillism. Modernists such as Pablo Picasso, Amedeo Modigliani, and Jacob Epstein were profoundly influenced by African art. Thus, by way of African art Western art was transformed to new abstract modes. Ironically, contemporary African art has had three corresponding periods of Western influence during the twentieth century: precolonial times, when traditional crafts and sculptures flourished; colonial times, which saw the development of Christian iconographic images, Western themes, and exotic media; and postcolonial times, during which several predominating styles emerged among contemporary African art composition.

By the 1940s some art lovers and missionaries urged a synthesis of African traditional styles alongside the modern ones. For example, Fathers Sean O. Mahoney and Kevin Carroll established a workshop school at Oye-Ekiti, Nigeria, where traditionally trained carvers were given evangelical themes from the Bible to execute in their own style. In this way, the Roman Catholic missions in Nigeria and in Zimbabwe became patrons of African traditional art that hitherto had earlier been condemned as fetish art. With this development, the common opinion that all African art products were fetishist oddities gradually gave way, restoring hope for the artists working in the traditional method.

Asian Visual Art

In the first half of the twentieth century Asian art, from Istanbul to Tokyo, shared one common feature: the onslaught of Western culture and the need for artists to absorb it while maintaining their own cultural identity. Often this created a bifurcation in the arts, such as Western versus native or modern versus traditional. But it also stimulated efforts to find a creative synthesis, a modern art with Asian, but more particularly national, character.

As in other things, Japan was the first Asian country to make this effort, to go beyond technological borrowing and search for the cultural basis for Western wealth and power. As early as 1876, Western oil painting was being taught in a government school in Tokyo. By the turn of the century there was a community of Japanese artists studying in Paris. In Japan, Yoga ("Western Painting"), mainly oil, was an officially recognized art form at government-sponsored annual exhibitions.

This enthusiasm for the new and foreign was, however, matched by a cultural nationalism that tried to modernize native Japanese art, brush and ink painting, by synthesizing Western and Japanese art. Ironically, the initial stimulus for this revalorization of native tradition came from one of the foreign experts hired to modernize Japanese art and culture. The American art theorist and critic Ernest Fenollosa urged the Japanese to appreciate the value of their own art and encouraged Japanese artists to free brush painting from the supposed effete conservatism of Confucian literati painting acquired from China several hundred years earlier.

The Asceticism of Uma, by Nandalal Bose, illustration from *Myths of the Hindus and Buddhists* by Sister Nivedita and Ananda Coomaraswamy, 1913. (Private Collection/The Stapleton Collection/The Bridgeman Art Library)

This message appealed to national pride and the desire to modernize, giving birth to a distinctively new genre called Nihonga (Japanese painting). Nihonga incorporated some techniques of Western realism, such as shading and fixed point perspective, but was still very self-consciously Japanese in an age of strong and pervasive nationalism.

Fenollosa's foremost Japanese disciple, Okakura Tenshin (1862–1913), was the movement's theorist and argued that Japan was the natural leader for a Pan-Asian cultural revival that would counterbalance Western materialism with Asian spirituality. These ideas also had some resonance in early-twentieth-century India, in particular among the intellectuals and artists who formed the Bengal School around

Rabindrinath Tagore. By no means traditional conservatives, in Japan, India, and elsewhere these new intellectuals sought to produce a creative synthesis that would be the foundation for a progressive reawakening in art and culture.

Pan-Asianism did bear some artistic fruit. Some leading Nihonga painters visited India, where their East Asian brushwork and particularly the slightly blurred misty effect obtained through light ink washes had an influence on some prominent modern Indian artists. The foremost was Nandalal Bose, an artist closely associated with Gandhi's Congress Party and the independence movement.

But there would be no significant Pan-Asian art movement. Twentieth-century Asian nationalists were too much concerned with their own particular cultural survival and with using art to promote nationalism to accept Japan's leadership, cultural or political. Further, Japanese military expansionism soon disabused them of any idea of following Japan's leadership.

This can be seen quite clearly in the history of the first group of Chinese painters to try to import the Nihonga style of modernized brush painting into China.

At the beginning of the century many Chinese revolutionaries had looked to Japan as a model for national rejuvenation in art as well as in other things. Up to the 1930s more Chinese artists studied Western art in Tokyo than in Paris. But in the early years reformed ink painting, Nihonga, also had its appeal. One group of young artists, also political activists in Sun Yatsen's revolutionary party, took the Nihonga blending of Eastern and Western art back to China and tried to promote a "New National Painting," Chinese in character (ink on paper) but incorporating Western techniques and modern subject matter.

Their attempt to combine Chinese and Western art had only limited success, and they became known as the Cantonese School (Lingnan Pai), from their province of origin. The Japanese flavor to their synthesis was a liability in appealing to Chinese nationalism.

In fact, throughout the republican period, from 1911 to 1949, Chinese visual art was rather sharply divided into the traditional ink painters, who mostly shunned foreign influences, and

► THE FEMALE ARTIST BETWEEN TWO WORLDS—PAN YULIANG

In the twentieth century, many young Asian artists went to Europe to study Western art. Although some stayed, most returned home to teach and practice in their native country. A very few made the long sea voyage more than once. These artists were pioneers and forerunners of an important phenomenon of the emergence of transnational art, cultural hybridity, and a nascent global culture. Although most of these cross-cultural pioneers were male, there were a few females, another new feature of Western globalization. One Chinese female oil painter, Pan Yuliang, was unique in her bifurcated life. She spent over 30 years in China in two separate periods, spending the rest of her life in Europe, mainly Paris. At home in two cultures and fluent in two languages, she led a life in two different social worlds.

Orphaned at a young age and sold into a brothel, the future artist was rescued by an official in the new Republican government, who took her to Shanghai as his second wife or concubine. There, through her husband's modern cultural connections, Pan (her married name) gained admission to the first coeducational art school in China, itself a controversial innovation in a society that had rigorously separated respectable young women from the public male world.

Pan's remarkable talent, especially in life drawing of the nude—another shocking Western innovation for traditional Chinese—earned her a government scholarship to study in Paris, where, after a hard financial struggle, she graduated from L'Ecole des Beaux Arts as a highly accomplished oil painter and sculptor in a rather conservative academic style.

Returning to China in the early 1930s, Pan had exhibitions and taught Western art, first in Shang-

hai and then as a professor at the newly established National Central University in Nanjing.

Despite success and recognition in China's modern cultural circles, rumors about her past life plagued her, and in 1936 she returned to Paris ostensibly for more experience at the center of Western art. But war and revolution intervened, and she spent the last 40 years of her life as an émigré artist achieving some recognition (a prize from the Paris city government, works in the Paris Museum of Asian Art, and works in the National Museum of Asian Art) but not a great deal of financial success. Sadly, Pan's life ended in poverty.

After Pan's death, just as China was reopening to the world in the late 1970s, her Paris works of art were brought back to China, a best-selling novel was written about her extraordinary life, and she became a national celebrity in the early 1980s, with art exhibitions in major cities, a widely watched TV miniseries about her life, and a movie starring China's most famous film star, Gong Li, as the global woman artist.

Was Pan Yuliang a great artist, unappreciated in life, discovered after death? Probably not. Although her substantial body of work that is not in Chinese museums has soared in value on the international art market as newly rich Chinese collectors have entered the scene, most of her oil paintings are rather ordinary by Western standards. However, the ink-on-paper studies of the female nude from her later Paris years combine Western anatomical training with Chinese brush technique in a successful fusion of Eastern and Western art, the goal of so many twentieth-century Asian artists.

—Ralph Croizier

young art students, who avidly studied Western art either abroad or in the new art schools, government and private, established in China's major cities.

But there were some ink painters who responded to the charge of stagnation by finding sources of innovation within China's long tradition of artistic creation. For example, during the Sino-Japanese War in the 1940s, the decidedly non-Western ink painter Zhang Daqian

(1899–1983) drew inspiration for bold coloristic innovations from the 1,200-year-old Indian-influenced Buddhist wall paintings in the caves at Dunhuang in the Gobi Desert. In the twentieth-century crisis of adjusting to cultural importations, these wall paintings served as a historical example of China successfully absorbing foreign influences.

Other Asian countries that had long been sources of cultural creativity for surrounding

areas faced similar problems in coping with Western influence. India had received a head start in absorbing Western art because of British rule, and by the mid-nineteenth century government-established schools were teaching Western art.

By far the most famous Indian artist to emerge under the Raj was Ravi Varma (1848–1906). He painted with oils in a highly polished and completely Western style that might be called Victorian romantic realism. But the subject matter was completely Indian: portraits of native Indian aristocrats and dramatized scenes from ancient Vedic literature and myths. Reproduced as cheap prints, this became by far the most popular form of art with the Indian masses, preserving traditional culture and religion while using Western art and technology to spread a new vision of ancient beliefs. Varma, with his financial success and popularity at all levels of Indian society, also established the social and cultural position of the artist as independent creator rather than servant to political or religious masters. By the middle of the twentieth century this new role for the artist was common across Asia.

But Varma did not challenge British rule or cultural hegemony. In the early twentieth century, awakening Indian nationalism inspired artists to seek out a more Indian style in painting. The first, and perhaps most successful, response to this came from the Bengal School and particularly the work *Mother India* (1905) by Abindrinath Tagore (1871–1951). A nationalist innovation—there is no such deity in Indian myth or religion—the multiarmed goddess drew on traditional Hindu iconography but was accurately Western in drawing while relying on soft colors and a misty effect, suggesting the superiority of Indian spirituality over Western materialism. *Mother India* became an icon of modern Indian art.

Over the next decades the central tension in Indian art was not so much traditional versus Western, as in China and to some extent Japan, but rather Western modernism versus the academic realism of the British established art academies. Some of the more interesting attempts at combining the bold simplified lines of modernism with Indian folk painting can be found in

the primitivist pictures of ordinary Indian women by Jamini Roy (1887–1974).

In the Islamic countries of West Asia, despite the Quranic discouragement of visual imagery, many of the issues and developments in the visual arts paralleled those in eastern and southern Asia. Ottoman Turkey was, in fact, one of the first countries to hire Western art teachers, significantly in military academies to teach scientific drawing. Under Mustafa Kemal (Ataturk) the new republic made vigorous efforts to catch up with Western art, with Turkish artists experimenting with everything from social realism to abstraction.

Cairo was the other major center for Western art and Western cultural influence before World War II, with an active modernist movement that tried to give modernism an Egyptian, Arabic, or even Islamic face. The same fundamental issue emerged across the continent: how to be modern without losing cultural identity. And behind that lurked another project: how to make art serve the cause of building national identity, another Western idea.

Dada

Dada was an informal artistic revolution that took place in Europe and the United States from about 1916 to approximately 1924. A multimedia antiart movement in art, literature, design, and music, Dada originated out of abhorrence and disgust at the bloodshed and destruction of World War I and was aimed by its protagonists at the total annihilation of art. The artists who created the movement, largely refugees from the war who were living in Zurich, Switzerland, included the Romanian poet Tristan Tzara, the German poet Richard Huelsenbeck, the Alsatian sculptor and painter Hans Arp, and the German writer Hugo Ball. They claimed that the traditional aesthetics, values, logic, and rationales of society had led to war; therefore, those qualities were without meaning and must be rejected. The Dada movement was abstract in that it evaded coherent description; it was also nihilistic in that every action and manifesto was about the refutation of traditional art and culture in favor of the absurd. Much of art during the subsequent decades of the twentieth century was influenced by Dada, including Surrealism, Abstract Expressionism, Pop Art, Conceptual Art, and Performance Art.

Accounts vary about the choice of “Dada” as the name of the movement. According to one version, the name was selected at random from a Larousse dictionary. Another account ascribes the name to a child’s first babbled words. Still another explains that the label came from the French word for “hobby-horse.” Whatever the origins of the name, Dada first came to public attention after February 1916 with the opening in Zurich of the Cabaret Voltaire, a venue at which the clientele witnessed spectacles of antiart. These spectacles included exhibitions of Dada artworks, recitation of nonsense poems by one artist or multiple artists simultaneously in different languages, defiantly absurdist musical performances of “African” music or arrhythmic drumming, and displays of outlandish costumes.

As Hugo Ball announced in the first Dada manifesto, read aloud to a gathering in July 1916, Dada was “outside all the parrotry of your self-evident limitedness.” All aspects of the prevalent culture were subject to parody, subversion, and distortion.

Reveling in the shock value of their compositions, the visual artists incorporated machinery, found objects, photographs, and scraps of paper or newsprint into their assemblages, as in Hans Arp’s *Collage with Squares Arranged according to the Laws of Chance* (1916–1917). Another striking example of this type is *Mechanical Head, or The Spirit of Our Time* (1919), the Austrian Raoul Hausmann’s wooden mannequin head adorned with a wallet, gears, measuring stick, and various other incongruous objects. Among the most notorious artworks of the era are two by the French painter and sculptor Marcel Duchamp, who incorporated what he termed “readymades.” These are *Fountain* (1917), a ceramic urinal placed on its back, and *L.H.O.O.Q.* (1919), a reproduction of Leonardo da Vinci’s *Mona Lisa*, with an added penciled mustache.

Dada poetry and literature were equally confrontational. Ball, Tzara, and Huelsenbeck wrote and performed works in which they used words in unexpected combinations and irrational contexts or presented *Lautegedichte* (sound poems) of nonsensical arrangements of syllables. They also wrote and proclaimed manifestos calling for the derangement of all conventions and the end to manifestos. In 1918 at the height of the movement, Tzara issued his own Dada manifesto, claiming, “In principle, I am against manifestos as I am against principles.” This contradiction is emblematic of work created in the name of Dada in that it was art that aimed at the eradication of art.

While the earliest manifestations of Dada took place in Zurich, the end of the war in November 1918 led many of the artists who had assembled in Switzerland to return to their homelands, taking the absurdist movement with them. Thus, Dada spread to Berlin, Paris, Barcelona, and New York, taking on a fresh momentum.

Duchamps and Francis Picabia went to New York, where they met Man Ray, one of the most innovative figures of the era. Man Ray (born Emmanuel Radnitzky), an American artist whose name is associated with both the Dada and

Surrealist movements of the twentieth century, was a photographer, writer, painter, designer, and sculptor. By 1920, Duchamp and Man Ray were collaborating with Katherine S. Dreier on the creation of the *Société Anonyme*, which sponsored exhibitions and lectures on modern art.

Dada in Berlin took on a more political tone in the aftermath of World War I with the atmosphere of civil war and the instability of the new Weimar Republic. Hannah Höch, George Grosz, John Heartfield, and Hausmann led the movement there, publishing a series of journals and producing the 1920 First International Dada Fair. Another artist of the Berlin movement was Kurt Schwitters, who broke away and created his own branch of Dada art, calling it Merz. In the early 1920s many of the Dada artists moved to Paris, where Dada was led by Guillaume Apollinaire, Max Jacob, and André Breton. By this time, however, Dada was waning, the victim of infighting and its own success.

As the avant-garde became fashionable, Dada teetered on the edge of respectability and threatened to become part of the art establishment. By 1922 the movement was waning in favor of Surrealism, and by 1924 Dada had given way to new trends in artistic expression.

Surrealism

The avant-garde phenomenon Surrealism was a cultural, literary, and artistic movement that began in Paris in the 1920s, following close on the heels of its predecessor, Dada, and spreading its

influence through the rest of the twentieth century. In the early 1920s when the bloodshed of World War I had ended, thus eliminating the initial source of Dada's momentum, many of the Dada artists resigned from the waning antiart movement. Surrealism provided a new focus for the avant-garde in their continued adherence to the irrational and revolutionary in art and literature. Though unlike Dada, which was nihilistic in its aim to reject art and traditional values, the newer movement was a positive trend, calling for creativity drawn from humanity's subconscious.

In his 1924 *Manifesto of Surrealism*, André Breton, a French poet and writer with some background in psychiatric studies, defined Surrealism as "psychic automatism in its pure state." The theoretical basis for Surrealism was the connection among the unconscious mind, dreams, and reality, a reflection of the influential role that Sigmund Freud's theories of psychoanalysis and dream interpretation played in the foundation of the movement. Freudian dream analysis had become a popular topic with readers after the 1913 publication of Freud's *Interpretation of Dreams* in its third edition, with the addition of some new and very literal interpretations of symbols. In Breton's manifesto, which established his position as the movement's principal figure, he argued for "the future resolution of these two states, dream and reality," into superreality. Breton's agenda identified poetry as the most appropriate medium for this automatism, though many of the movement's most well-known examples over the decades have been in the visual or plastic arts.

Breton named the contemporaries whose work he considered Surrealist in the 1924 manifesto, describing the group as inhabitants of an imaginary castle. His lists included Louis Aragon and Philippe Soupault, with whom he had founded the journal *Littérature* in 1919, as well as Paul Eluard and others. Pablo Picasso is mentioned but only as a hunter nearby the castle in the woods. Breton also listed a number of Surrealists as qualified in distinctive areas, identifying the Marquis de Sade as "Surrealist in sadism" and Charles Beaudelaire as "Surrealist in morality." According to Breton, "We really live by our fantasies when we give free reign to them." The poetry written under the Surrealist standard was

full of the same sort of fantastic imagery that leapt from dreams to the unfettered imagination, as in Breton's poem "Freedom of Love" in which he describes his wife's "eyes of purple panoply and of a magnetic needle."

Surrealism as a cultural revolution provided a rich field for visual artists as well, including Man Ray, Max Ernst, Joan Miró, René Magritte, Salvador Dalí, Marc Chagall, and Paul Klee, many of whom participated in the first group exhibit, *Exposition, La Peinture Surréaliste*, in November 1925 at the Galerie Pierre in Paris. One of Joan Miró's earliest Surrealist paintings was *The Tilled Field* (1923–1924), a work in which the Spanish artist incorporated many disparate images of animals and farm implements on a bright yellow ground, drawing upon fantasies of his childhood on his family's farm in Catalonia. Magritte's *The Treachery of Images* (1928–1929) is a painting of a tobacco pipe labeled in French "This is not a pipe." Magritte, a Belgian painter, became known for his visual contradictions, which flouted the connections between images and words. In another of his works, *Golconda* (1953), the sky is filled with identical floating businessmen in overcoats and bowler hats. One of the most famous Surrealist paintings is *The Persistence of Memory* (1931) by the Spanish artist Salvador Dalí. In this haunting and bleak landscape, melting clocks droop over the edge of a table, the branch of a tree, and a rubbery body that may be a fish or a man. All of these works are rife with ambiguity even to their titles, which reveal little of the works' meanings.

The Surrealists adopted social revolution and ambiguity in a more political sense as well, and many of them became members of the Communist Party in the late 1920s. Ultimately, however, the Surrealists and the communists parted ways after only a few years, unable to agree on their brands of political activism. The Surrealists criticized the stultifying conformity of Soviet communism, and in 1933 Breton, Eluard, and others were expelled from the party. They responded in 1935 by publishing *Bulletin International du Surréalisme*, which proclaimed their censure of the Soviet Union.

By the outbreak of World War II, many of the major Surrealists had left Europe, including Breton, Ernst, and Dalí. Surrealism increasingly

took hold in New York, particularly with the patronage of the wealthy art collector and gallery owner Peggy Guggenheim. Eventually, the irrationality of Surrealist images and the rejection of traditional rules of art and literature that characterized Dada and Surrealism created the climate in which Abstract Expressionism, the first truly American modernist artistic movement, could thrive.

Abstract Art

Abstract art, as a movement, began in the early twentieth century. A worldwide phenomenon, it was a movement defined as being free from representational qualities; in this sense the movement and its goals were both idealistic and visionary. It evolved at a time of great change in the world, especially with the increased mechanization of the workforce, the breakthroughs in science, and the advances in photography and film. This was also a time during which there was a sense of fascination with anything new, especially following World War I. The modernist movement in literature and the arts, of which abstract art was an offshoot, was a revolt against the old order and its certainties. Instead, spontaneity, new perspectives, and subconscious processes were valorized.

Abstract Art was distinguishable by its non-representational form, color, and texture. The movement seemed to be a natural progression from the Impressionists and their use of color that was different from the traditional European

WASSILY KANDINSKY (1866–1944)

Wassily Kandinsky, one of the leading innovators of the abstract art movement in the twentieth century, did not start painting until his early thirties. He studied at the Academy of Fine Arts in Munich (1896–1900), where his early paintings were naturalistic. Then in 1909 he attended an exhibition of the French Impressionists, sparking an interest in new approaches to representation. Subsequently he founded the art group *Der Blaue Reiter* (1910–1914) with artists Franz Marc and August Macke and was heavily influenced by the French Impressionists as his paintings became more abstract. Impressionism showed Kandinsky that he could strip away the detail to find the color, lines, and shapes, which then could be interpreted individually by the viewer while also portraying the inner emotions of the artist.

Kandinsky also belonged to the German art and design school Bauhaus (1922–1933), teaching design and painting while theorizing about visual art and its relationship to other arts. His two major publications were *On the Spiritual in Art*, promoting abstract art and the use of color, and *Paint and Line to Plane*, dealing with the importance of line and geometrics. In his writings he also explored the correlation between art and music. He was fascinated with the emotional power that music provided the listener: freeing the mind to interpret the piece as an individual experience. Kandinsky wished to

Wassily Kandinsky's *Composition IX* (1936).
(CNAC/MNAM/Réunion des Musées Nationaux/Art Resource, NY)

translate this process to his paintings. He believed that music and color allowed him to portray subjects according to his knowledge of them and not what his eyes actually saw. He used very intense color in his paintings to indicate the different moods of his works, for example *Yellow-Red-Blue* (1925). The use of geometric shapes became more important in his paintings together with the intense use of color, and as his works progressed his visions became more complex, such as in *Composition IX* (1936) and *Composition X* (1939). For Kandinsky, painting could reproduce spiritual experience.

—Shelley G. Allsop

style of image reflection. Abstract Art also developed from the short-lived Fauvism style that had introduced the use of brilliant colors and broader brushstrokes. The trend became one of “art for art’s sake”; it was all about the process and end result, not necessarily the subject matter. The artists used their materials as their inspiration rather than starting with a preconceived idea as to what the end product should look like. Abstract Expressionism is the extreme example of this, and its ultimate voice is the action painting style of Jackson Pollock (1912–1956), with its canvases covered spontaneously with splatters and drips.

The forerunner to the Abstract Art movement was cubism, in which artists started to paint in a flattened fragmented style, with geometric renderings that captured movement and

multiple perspectives. Although there were experiments with limited color palettes, nature was still represented. Instead of turning to total abstraction, cubists chose to experiment with collage, thus retaining a part of the real world in their art. Others were developing more colorful and geometric alternatives. For example, Robert Delaunay (1885–1941) and Frantisek Kupka (1871–1957) painted totally abstract paintings to reflect their deep interest in color and shape with an interest in the use of light and its impact on color. They experimented with the power of color and light to suggest movement.

After something new and vital, the pioneers of the Abstract Art movement, Wassily Kandinsky (1866–1944), Kasimir Malevich (1878–1935), and Piet Mondrian (1872–1944), moved away

from cubism, which they believed still represented natural images rather than imaginary ones. The progression was toward using geometric shapes that were not present in nature in their pure form, such as the square, the triangle, and the circle.

Within the Abstract Art movement two basic categories existed—organic and geometric—although neither category was exclusive. Organic Abstract Art incorporates symbols derived from nature and the subconscious and had much in common with Expressionism. The geometric style, however, was deemed the purer form of abstraction. Malevich created the first truly Abstract painting, which was a simplistic completely geometric painting of a black square on a white background. He called his style Suprematism to reflect the importance of the shape over the background. He developed further into Constructivism, in which forms were defined by pure precision. Mondrian's work was even more precise than that of Malevich, with the former using black lines in grid patterns with asymmetrical areas of primary colors. He termed his style Neoplasticism, turning away from natural forms altogether. Kandinsky's works moved from the organic to the geometric (although more fluid); his paintings began to reveal huge expansions of color intersected with lines, circles, squares, and triangles.

The philosophy of the Abstract Art movement was spread through gatherings of like-minded artists, through salons and schools, and through new artistic periodicals. The most recognizable of these institutions were the Dutch artistic journal *De Stijl* (*The Style*) and the Bauhaus art school in Germany. In his 1912 *Über das Geistige in der Kunst* (*Concerning the Spiritual in Art*), Kandinsky proposed the philosophy that colors and emotions were linked.

The Abstract artists wanted to produce works that were on one end of the scale spontaneous and extreme and on the other end completely structured as to depict “purity” in form, color, and line. Despite the vast variety of artists and works represented by Abstract Art, they all adhered to the movement's basic philosophy: art is meant to excite and be both by and for the imagination of the artist and the viewer.

Muralism

The muralist movement began in Mexico in the 1920s. It germinated in the climate of the Mexican Revolution, which erupted in 1910 as a response to the long dictatorship of Porfirio Díaz (1876–1910). After a decade of turmoil, José Vasconcelos, the minister of education during the Alvaro Obregón administration (1920–1924), envisioned using public works to bolster national stability. As part of this program, Vasconcelos commissioned artists, many of whom had fled the country during the violence of the revolution, to create nationalistic murals. The three most prominent muralists were Diego Rivera (1886–1957), José Clemente Orozco (1883–1949), and David Alfaro Siqueiros (1896–1975). Starting in the 1920s, these artists, often referred to in literature as *los tres Grandes*, gained national and international attention for their paintings, which adorned the walls of some of Mexico's most important buildings.

Rivera, a child prodigy, started as a traditional easel painter. Recognizing his talent, the Mexican government awarded Rivera a grant to study art in Europe, where he honed his skills in cubism. After an extended period abroad he returned to Mexico in 1919, at which time he was recruited by Vasconcelos. Rivera incorporated imagery that spanned the entirety of Mexican history from the pre-Columbian world of the Aztecs to the revolutionary leaders of the early twentieth century. At the same time his murals, as well as those created by other artists, served as sounding boards for political, religious, and other ideological material.

Orozco lost a hand and suffered permanent sight and hearing damage from an explosion, and thus his work was fueled by personal tragedy. Prior to working on Vasconcelos's mural projects, Orozco had garnered attention, often

negative, for his depictions of schoolgirls, prostitutes, and political caricatures. Stylistically, he differed significantly from Rivera. However, Orozco's murals focused on similar content, including the Mexican Revolution, socialist propaganda, and Mexican historical figures.

Siqueiros, the youngest of the three prominent muralists, participated in the Mexican Revolution, witnessing its horrors firsthand. A pronounced Stalinist, he also fought for the Republican Army in the Spanish Civil War and later led an unsuccessful attempt to murder Leon Trotsky, who had sought exile in Mexico. Siqueiros's murals were stridently political and filled with socialist imagery. Some of his greatest artistic achievements came from his advocacy of experimentation with new techniques in mural art, including the use of synthetic mediums and the integration of sculpture to create a medium known as *escultopintura*.

As enthusiasm for mural art spread throughout the Americas during the 1930s, artists in the United States took up the medium. The Works Progress Administration (WPA), created by Franklin D. Roosevelt during the Great Depres-

sion, commissioned artists to paint murals to promote nationalism and unity. Rivera, Orozco, and Siqueiros also visited the United States during this period and not only served as inspirational figures for fellow artists but also worked on mural projects in major cities such as Detroit and San Francisco. One of the most prominent U.S. muralists of the WPA period was an African American, Aaron Douglas (1899–1979). A major contributor to the Harlem Renaissance, Douglas gained prominence for his visions of African American life during the 1930s. Some of his best-known murals include the WPA-sponsored project at the 135th Street Branch of the New York Public Library and his work at Fisk University in Nashville, Tennessee.

The period between 1920 and the end of World War II was arguably the apex of mural painting in the Americas. In the United States, mural art has remained particularly popular among inner-city communities made up of Latino and African American populations. Likewise, the muralists inspired a generation of painters and were the precursors to modern graffiti artists.

Social Realism in Visual Arts

Social realism reflected and expressed many of the central tensions, political and social, in the tumultuous decades of war and revolution that marked the first half of the twentieth century. Although social realism had roots in European

art from the middle of the nineteenth century on, its greatest impact in art and politics came in the period between World War I and World War II, 1919 to 1939. Social realism was also mainly a Euro-American phenomenon, most significant in the USSR and the United States, although it had echoes and reverberations in the colonial and semicolonial world.

The term “social realism” can be confusing, for it is sometimes applied to the official art from Stalin’s Soviet Union, where instead of exposing social ills, art supported the state and its policies by showing only positive developments and the happiness of the masses. This was in one sense a continuation of the original impulse behind social realist art: to dignify the common people and promote social change. But as the official art of the USSR and other communist countries after 1945, it became state propaganda rather than critical art, more wishful thinking than realism.

Realism—the apparently accurate portrayal of visual images on a two-dimensional surface—had a stronger tradition in European art than in any other sophisticated visual culture, especially since the Renaissance. Common people and their social condition were not common subjects, however, until the nineteenth century. Gustave Courbet (1819–1877) is often cited as the most important figure in this movement, and his 1851 monumentalization of common labor, *The Stonebreakers*, was the beginning of what was a subversive trend rather than an organized movement in nineteenth-century Europe. The painting reflected both the emancipatory ideals of the French Revolution (by no means confined to France) and the social tensions accompanying industrialization.

Probably the most coherent and influential social realist movement emerged in tsarist Russia with a group of young painters who forsook the classical themes taught at the Imperial Art Academy and took their scenes of everyday Russian reality, often brutish and backward, on a series of unofficial exhibitions in various Russian cities, hence the name given this group, *Peredvizhniki* (The Wanderers).

The *Volga Boat Haulers* of 1870 by Ilya Repin (1844–1930) is perhaps the most famous and potentially subversive of this group’s paintings. It shows bedraggled and exhausted peasants

hauling a barge up the Volga, with one strikingly blonde young man rising from the tow ropes as if looking to the future for liberation. From the 1860s to the 1880s, The Wanderers had a major impact on Russian art and social consciousness, but by the end of the century patronage from newly prosperous Russian capitalists and eventual recognition by the imperial state had taken most of the sting out of their potentially revolutionary message and co-opted them to the force of Russian nationalism.

In western Europe, and in Russia itself at the beginning of the twentieth century, the artistic “left”—painters, print makers, and pioneers in the new technology of photography—inclined more toward emerging modernist styles and techniques even when conveying a social or political message. Starting during the agony of World War I, the Dada movement was anything but realistic in a conventional sense, and neither was Surrealism in the interwar decades. Some of the most potent social and political art came from post-World War I Germany: Kathe Kollwitz’s grim prints of lower-class suffering, George Grosz’s savage caricatures of the ruling classes, and George Heartfield’s satirical photomontages. But in style, all of these leaned toward expressionist exaggeration rather than toward realism.

More conventional realism gained greater traction in the Depression-era United States, where both New York’s so-called Ash Can School of the 1910s–1920s and the Regionalists from the Midwestern heartland had laid the groundwork for a distinctively American social art. By the 1930s a genuine social realism had emerged, with artists such as Ben Shahn, Philip Evergood, and Reginald Marsh portraying the hopelessness of unemployment lines and soup kitchens. Some of the most powerful and lasting images of the impact of the Great Depression on ordinary people’s lives came from realist photographers such as Walker Evans and Dorothea Lange, who took photography out of the artist’s studio into the real world of poverty, privation, and despair.

This art and photography emerged along with social realism in literature, such as the brief popularity of the proletariat novel as well as sociological studies and documentary journalism that focused on the struggles and heroism of members of the underclass (such as industrial

➤ BEN SHAHN AND ALEXANDER DEINEKA—AMERICAN AND RUSSIAN REALIST PAINTERS IN THE 1930s

Unemployed, by Ben Shahn, 1938. (The Bridgeman Art Library/Estate of Ben Shahn/Licensed by VAGA, New York, NY)

The life spans of Ben Shahn (1898–1969) and Alexander Deineka (1899–1969) match almost perfectly, and their respective careers tell a great deal about the tight association of art with politics and social change in the first half of the twentieth century.

Both came from relatively humble backgrounds and maintained a lifelong connection to the lives and welfare of common people. Both became involved in political causes. Shahn's political involvement began as a critic of injustice and prejudice in his series of pictures, 1931–1932, on the murder trial and execution of the Italian immigrant anarchists Sacco and Vanzetti, and continued in his work as a mural painter for the New Deal's Works Project Administration (WPA) and a photographer for the New Deal's Farm Security Administration. Deineka worked as a propaganda artist for the new Bolshevik government after the revolution and then as an official painter of socialist achievements in the USSR. Like Shahn working for the WPA, Deineka did public art, designing mosaic murals for the Moscow subway system.

There the similarities stop, and the differences show that American social realism and Soviet socialist realism were very different. Shahn's art, for all its gritty realism in printmaking, easel painting, and photography, showed affinities for modernist simplification and flattening of the picture surface. His group portrait *Unemployed* (1938) is representative of his Depression-era

work, combining sympathy with condemnation of the system that inflicts this misery.

Deineka moved in the other direction. The modernist flattening so pronounced in his early work and derived from his affinities with the Russian avant-garde around the time of the Russian Revolution almost disappears once the Communist Party has proclaimed socialist realism in 1932. One of his more monumental and propagandistic works is *Heroes of the First Five Year Plan* (1936). A phalanx of six laboring types—including peasants, ethnic minorities, and liberated women—march forward with a monumentalized worker figure at the head. Overhead, in a blatant rejection of all modernist sensibilities, the classical Greek statue *Winged Victory* flies over the heroes of the new age. Although the direct propaganda content in his art diminished somewhat after Stalin's death in 1953, Deineka continued to present the labor heroes of the Soviet Union in larger-than-life poses, as in his *Tractor Driver* of 1956.

Both Shahn and Deineka painted ordinary people, the concern of social realists, but one painting is critical of the society, and the other is celebratory. There is the difference between social realism and socialist realism.

—Ralph Croizier

Tractor Driver, by Alexander Deineka, 1956. (DACS/RIA Novosti/The Bridgeman Art Library)

workers, hoboes, and sharecroppers). While the taste for social realism and activist art came first, many artists and writers were influenced by the 1935 Popular Front directive of the Seventh World Congress of the Comintern. The Popular Front encouraged efforts to bridge the distance among hard-line communists, socialists, and liberals in the West to fight against fascism and to support labor and other social causes.

Despite this declaration of common cause between the Soviet Union and Western artists and writers, contemporaneous socialist realism in the USSR, proclaimed as official art policy in 1932, bore a similarity only in name and to some extent in the common people it portrayed. To be sure, art had government support in the United States under the New Deal's program to provide employment for artists doing murals and other public art for the Works Project Administration. But American painters were not under the same type of political control as their Soviet counterparts, and there were other outlets for socially critical art in the United States.

In the USSR, stock socialist realist subjects consisted of sturdy workers exceeding production quotas, happy peasants celebrating agricultural collectivization (at the same time as millions were starving from Stalin's agricultural policies), and, furthest from the spirit and goals of original social realism, heroic portraits of communist leaders, including Lenin and especially Stalin. In contrast to the dark tones of most social realist pictures, Soviet social realism usually showed the workers' paradise in bright, cheerful colors. The technical ability of some of the leading socialist realist painters, such as Isaac Brodsky, Alexander Gerasimov, and Alexander Deineka, is indisputable; however, by the canons of modern art, they were painting in an academic realist style that was long out of favor. It remains to be seen if postmodern art historians will look upon their work any more favorably.

Before it became the official and only permitted art style in the new communist countries after 1945, socialist realism had little appeal abroad—some echoes in proletarian art in Japan and the left-wing art movement in China—but generally speaking the style was too conservative for left-wing artists. This can be seen in Latin America's most famous social-political art,

the muralist movement from the 1920s to the 1940s. This movement's most famous figures, such as Diego Rivera, Jose Clemente Orozco, and David Siqueros, were sympathetic to Marxism but took nothing from Soviet-style socialist realism. Perhaps another communist sympathizer, on another continent, put it best when Pablo Picasso allegedly commented, "I don't tell the Soviet commissars how to do politics; they don't tell me how to paint."

On the other side of the artistic-political divide in the postwar United States, social realism faded into the background as the prosperity of the 1950s removed much of social art's *raison d'être* and new modernist styles—abstract expressionism, color field painting, and minimalism—took over the art market. Social realism became outdated, or out of fashion, and socialist realism only survived as long as orthodox communist governments could enforce it. North Korea is perhaps the last surviving example.

The Bauhaus School

The Bauhaus in Germany (1919–1933) was one of the most influential art and design schools of the twentieth century. Founded just after the end of World War I, on April 1, 1919, in the city of Weimar, its modernist approach, including the teaching of the hence unknown abstract art and the new architecture, caused so much controversy that various factions including artisans, Weimar artists, and emerging right-wing groups forced the Bauhaus from the city just a few years later. In 1925 it moved to Dessau and seven years

► THREE BAUHAUS LEADERS

Walter Gropius (1883–1969), founder of the Bauhaus, was a famous pioneer of modern architecture and design. Due to his inability to draw, he always collaborated closely with partners such as Adolf Meyer, with whom he made important contributions to the New Objectivity movement. Gropius immigrated to the United States in 1934 and later became a professor at Harvard University. In America he founded The Architects Collaborative, Inc. (TAC). Important Gropius buildings include the Fagus Factory in Alfeld, Germany (1910–1911); the Bauhaus buildings in Dessau (1925–1932); the Harvard Graduate Centre (1949–1950); the University of Baghdad (1957–1960); the Pan Am building in New York City (1958–1963); and the U.S. Embassy in Athens, Greece (1959–1961).

Hannes Meyer (1889–1954) was a Swiss architect. He joined the Bauhaus in 1927, created an architectural class, and took over as director one year later. During his two years as director he built apartment buildings in Dessau and also the ADGB (Allgemeiner Deutscher Gewerkschaftsbund) trade union school in Bernau, near Berlin, in

which many Bauhaus workshops were housed. After the Bauhaus, he went to Moscow to continue his work. In 1936 he moved to Mexico and worked for the government before he retired in Switzerland.

Architect Mies van der Rohe (1886–1969) had a style characterized by simplicity, classic proportions, and luxurious materials. His minimalist approach was influenced by architect Peter Behrens, chef designer of Allgemeine Elektrizitäts Gesellschaft (AEG), which produced electrical equipment. He worked at AEG as an apprentice, as had Walter Gropius and Le Corbusier. Van der Rohe immigrated to the United States in 1938 and continued his work as head of the Department of Architecture at Chicago's Armour Institute of Technology. Among his best-known buildings and iconic works are the Villa Tugendhat in Brno, Czech Republic (1930); the residential towers at 860–880 Lake Shore Drive (1949–1951); the Farnsworth House (1945–1951); Crown Hall (1950–1956) in Chicago; and the Seagram Building in New York City (1954–1958).

—Anja Baumhoff

later to Berlin, where the National Socialists initiated its final closure in 1933. Its radical and controversial impact was due to the fact that it was the only art school at the time that taught exclusively modernist art such as abstract painting, design, and architecture. Its three directors were the architects Walter Gropius, Hannes Meyer, and Mies van der Rohe. Among its masters were eminent modernist artists such as Lyonel Feininger, Wassily Kandinsky, Paul Klee, László Moholy-Nagy, Herbert Bayer, Marcel Breuer, Wilhelm Wagenfeld, Anni and Josef Albers, Oskar Schlemmer, Marianne Brandt, and Gunta Stölzl.

Conceptually, the school followed new ideas, many of which had been developed by the German Werkbund (Work Federation), in that it combined an arts and crafts school with a fine arts academy. Wanting to unite all the arts and crafts into a total work of art (a *Gesamtkunstwerk*) under the leadership of architecture, they intended not only to produce a new design but

also to create a new world. What the Bauhaus actually created was a new profession, that of the designer, a term that only made its way into the German language after World War II when this profession slowly gained more recognition.

The Bauhaus's importance rests on its relentless promotion of the idea of modernism, making it a controversial focal point for debate during the economic crisis and the stormy political developments of the Weimar Republic. The Bauhaus under Walter Gropius's leadership endorsed Abstract Art at a time when this form of representation was not well accepted as art. When the school hired some of its most significant representatives, such as Feininger, Schlemmer, Klee, and Kandinsky, this caused further dismay. The Bauhaus propagated not only modern architecture but also a new style of life and, correspondingly, a new interior design at a time when people still preferred eclecticism and heavy, velvety drapes surrounding opulent furniture. Eclecticism commonly identified a style that also

implied a set of bourgeois tastes and way of life. While most manufacturers wanted to continue to individually produce this kind of ornate interior design, Bauhaus members participated in the development of the Deutsche Industrie Norm (DIN), which aimed to standardize the construction and design of buildings as well as furniture to aid less-expensive mass production. This would put out of work manufacturers who oftentimes attacked the Bauhaus movement in the contemporary press. The Bauhaus responded by publishing ideas of their own in a series of 14 books, the so-called *Bauhausbücher*, and in the *Bauhaus Journal*.

The Bauhaus reflects more or less all of the different tendencies of the Weimar Republic. In its early days, between 1919 and 1923, it was still very much influenced by Expressionism and had a strong spiritual component with the Mazdaznan life reform movement. Bauhaus master Johannes Itten was a follower of this sect, which prescribed vegetarianism, fasting, breathing exercises, and other disciplines. The title of master, which was used to refer to teachers in the school, connected the Bauhaus to the influential medieval tradition and Gothic forms that influenced its early phase. The idea of a total work of art (*Gesamtkunstwerk*) also belongs to this phase.

Once Johannes Itten left the Bauhaus in 1923 and the Hungarian constructivist László Moholy-Nagy took his post, the school changed directions. The road to this change had been paved by the Dutch artist and writer Theo van Doesburg, founder of the Dutch De Stijl group that had strongly influenced the Bauhaus since 1921. Others, such as the influential architectural critic Adolf Behne, also urged the school's director to turn away from Expressionism and the arts and crafts and to focus more on industry. Gropius thus put out the slogan "art and technology, a new unity." This dictum, in combination with Louis Sullivan's motto "form follows function," led to the reduction of design to minimalist forms, including the use of simple black and white interiors as well as simple basic colors. All of these elements combined capture the popular interpretation of the Bauhaus legacy still current.

But the Bauhaus was about more than simple geometric forms, flat roofs, or polished interiors. When Walter Gropius left the institute in 1928

he was succeeded by the Swiss architect Hannes Meyer, who had a more radical approach and reformed the school's program in order to promote more socially responsible design. The Bauhaus, Meyer thought, should help to improve the living conditions of the poor, raise hygienic standards, and build affordable houses. He captured this in the slogan "Volksbedarf statt Luxusbedarf" ("to design for the masses and not for the rich"). During Meyer's brief time as director, from 1928 to 1930, the Bauhaus workshops focused on industry and mass production. He also established the first workshops that taught architecture specifically in 1927 and a much-longed-for photography workshop in 1928. They complemented the other workshops in Dessau, which included typography and advertisement, carpentry, metal, weaving, wall painting, sculpture, and a stage workshop. The more arts and crafts-oriented workshops, such as pottery and bookbinding, remained in Weimar.

Although Meyer was quite successful, he lost his position in 1930 to Mies van der Rohe due to the rising right-wing forces. In order to save the Bauhaus from its political opponents, Mies van der Rohe tried to calm the school's intense political discussions, but he could not prevent the National Socialists from closing down the school. However, becoming a prominent victim of the new fascist regime turned out to be a stepping stone for the posthumous international fame of the Bauhaus.

As an architectural school, the Bauhaus was always a predominantly male institution, but even so, one-third of its 1,250 members were female. Women mainly worked in the weaving workshop, the pottery workshop, or the bookbinding workshop. Exceptions included Marianne Brandt, who was a member of the metal workshop, and Alma Buscher, who designed children's toys. Despite the rather conventional gender stereotypes present at the Bauhaus and within the modern movement in general, many courageous female artists left their mark during that time.

Modernism in the Visual Arts

Modernism in the visual arts is closely linked to the idea of modernity and also to industrialization and constitutes a shift away from production within the traditional academy system to works made by increasingly individualistic yet usually movement-identified artists who for the most part sold their works through private dealers. Because modernist visual art is both relatively recent and old enough to have entered the canon—work created in the present day is now called postmodern or contemporary rather than modern—modernist works remain new and startling to many viewers while providing a reference and starting point for contemporary artists. Art movements from the early stages of modernism, such as Impressionism and Fauvism, are now so widely accepted that favorite works from these movements now adorn countless mugs, umbrellas, and tote bags.

Thus, while every era in history has probably seen itself as new and up-to-date, artistic modernism can be seen as involving a special preoccupation with ideas of modernity, change, and modernization as opposed to ideas of tradition, continuity, and the historical. This was in part due to the extensive social changes that occurred with industrialization over the course of the nineteenth century, which prompted changes in both urban and rural life and brought about both the entrenchment and important critiques of capitalism. It is not surprising, then, that the mid-nineteenth-century writer Baudelaire's text "The Painter of Modern Life" (1859) remained significant for artists long after precise visual depictions of urban life ceased to be considered very modernist. Whether the artist was a nineteenth-

century Impressionist examining the Parisian bourgeoisie or a twentieth-century Surrealist working with ideas of the Freudian unconscious, modernity and modern life have been the fundamental underpinnings of modernist visual art. Changes in technology, such as the invention of photography and cinema along with new methods of color printing, also encouraged visual artists to think about their work in new and radical ways.

The importance of industrialization and social change explains why artistic modernism was strong under both capitalism and early Soviet communism. Ideas relating to the effects of industrialization, capitalism, and social class have been underlying themes vital to many modernist movements, whether one looks at the fin-de-siècle Decadents' preoccupation with sexuality and degeneration, the Futurists' desire to sweep away the past in favor of a speeded-up technological future, or the Russian Constructivists' interest in deposing "easel painting" in favor of an art that would be simultaneously built in the physical sense and that would help build the new classless communist society. Although modernist movements received some support from sympathetic critics and forward-looking patrons, in general modernist art was not immediately well received by either the art press or the general public. The average person, even if excited by the invention and availability of cars, planes, telephones, and radio or by the spread of movies, jazz, and short skirts, also wanted some degree of familiarity.

From 1900 to 1945, rapid formation and equally rapid dissolution were typical of modernist movements. Analytical cubism, developed by Picasso and Braque in 1907, quickly fascinated the art world with its fracturing of the picture plane into a kind of visual puzzle, but it was soon supplanted by synthetic cubism, which relied on an additive collage-influenced method of composition. Numerous forms of cubism soon came into existence, and these did not necessarily look much like one another. Fernand Léger's version was not greatly like that of Marcel Duchamp, and among the Czech cubist painters, there was heated disagreement over whether their cubism should closely follow in the footsteps of Picasso and Braque or should be free to go in other directions. Cubism's enormous influence in the art

world also prompted the birth of such short-lived but significant movements as Italian and Russian Futurism, Orphism, Rayonnism, and Constructivism and heralded the way for nonobjective art.

Nonobjective art, which began to be created sometime around 1910 by Kandinsky (working in Germany and Russia) and Kupka (working in France) in their search for a means to more perfectly express spiritual and mental concepts and states, was a direction taken up by relatively few modernist artists until the Abstract Expressionist movement of the 1940s and 1950s. Among the few artists to work in a truly nonobjective manner were Malevich (in some of his Suprematist paintings such as the *Black Square*) and Mondrian (in his neoplasticist works). Most works that at first glance appear to be nonobjective are in fact highly abstract works that do represent some sort of physical object. Art that falls into this category includes the work of Miró, which although appearing to consist of random biomorphic shapes is actually composed of carefully simplified representations of entire and often complex scenes. By the middle of the twentieth century, however, nonobjective art would become the focus of praise by influential formalist critics, notably Clement Greenberg who argued that this rejection of pictorial representation simultaneously posed an opposition to capitalist culture and concentrated on essential formal qualities. Greenberg argued, in short, that content (meaning) was no longer of importance in painting and that form was paramount. At the same time, however, the U.S. government was using Abstract Expressionist painting to advertise the freedom allowed American painters under capitalist democracy. American artists were free to throw paint at the canvas and sell the result to the highest bidder.

Most twentieth-century modernist art was not, however, nonobjective and in fact often dealt with very explicit social and political themes. While Dadaism, for instance, has often been characterized as destructive and nihilistic, it came into existence largely as a response to World War I, and the Berlin Dada group specialized in sociopolitical comment and satire. Much 1920s modernist art indeed examined postwar society, whether from the jaded viewpoint of an Otto Dix or the more celebratory works cre-

➤ CZECH CUBIST ARCHITECTURE

Cubist architecture developed in only one area, the Bohemian lands of Austria-Hungary (now the Czech Republic). Inspired partly by cubist painting, it also drew on ideas from earlier Czech architecture, such as the Renaissance Letohrádek Hvě zda (Star Summer Palace) and the works of Baroque architect Jan Blažej Santini Aichel.

Pavel Janák's treatise "The Prism and the Pyramid" (1911) advocated architecture that employed non-right-angled construction, especially the use of crystalline forms. The first cubist building, Josef Goč ár's House of the Black Madonna (1911–1912), a department store in central Prague, now houses the Museum of Czech Cubism. The House of the Black Madonna was required to be visually compatible with its baroque neighbors, so its facade and roof combine traditional and cubist elements, while its interior is more strictly cubist. Goč ár, Janák, and Josef Chochol are considered the three main cubist architects, but many others designed cubist buildings that were never constructed.

—Karla Huebner

ated by the African American artists of the Harlem Renaissance and the Czech avant-gardes of the Devě tsilgroup. Likewise, Mexican muralists such as Diego Rivera, David Siqueros, and Jose Clemente Orozco emphasized a combination of nationalism and strongly Leftist politics. And while Surrealist art seldom directly addressed sociopolitical themes, artists within that movement sought to express internal reality, working from a so-called internal model whose exploration was regarded as vital to a modern and scientific understanding of the human psyche.

With form, content, and innovation being regarded by most modernists as vitally important, it is not surprising that modernist architects also sought a melding of form and content through innovation. Frank Lloyd Wright and the Prairie School, Walter Gropius and the Bauhaus, the Functionalists of the 1930s, and the International Style of Le Corbusier and Mies van der Rohe all sought, in differing ways, a simplification of form and an attention to use of space.

Art Nouveau

"Art Nouveau" is a term used to describe an artistic movement that manifested itself between about 1890 and 1910 in the fine and decorative arts and architecture in Europe and the United States and subsequently in other parts of the

world. The movement is named after the shop opened in Paris in 1895 by art dealer Siegfried Bing, who exhibited and sold furniture, textiles, ceramics, glass, and jewelry in the new style. It is also known as Modern Style in Great Britain and the United States, Stile Floreale (Floral Style) or Liberty in Italy (named after the London shop Liberty's), Arte Joven or Modernista in Spain, Jugendstil (Youth Style, after the Munich magazine *Jugend*) in Germany, Secessionstil in Austria, Velde Style in Belgium, and Style Sapin (Fir Tree Style) in Switzerland. Art Nouveau does not represent a coherent style but instead designates the modern art of the time, which wanted to break free from tradition and from the revivals that had characterized most of the arts of the nineteenth century.

The lack of an original and contemporary style, which would not consist of merely copying the arts of past centuries, was already at stake in the first years of the nineteenth century. As early as 1836, the French poet Alfred de Musset deplored this situation in his *Confession d'un Enfant du Siècle* (*Confession of a Child of the Century*). Art Nouveau would thus appear as a much-awaited solution to a long-unresolved problem. Although it had the taste of novelty, Art Nouveau was influenced by a series of previous artistic experiences, such as the Gothic revival, Japonisme, the Rococo revival, the Arts and Crafts movement, and the Aesthetic movement. In addition to these, artists turned to the study of nature for fresh inspiration, as had architects and designers such as Owen Jones in Great Britain and Viollet-le-Duc in France.

Art Nouveau artists sought the perfect unity of the arts, encompassing all artistic manifestations from architecture to fashion and furniture in order to achieve a total work of art. This vision led them to design everything, from the general structure of a building to the smallest details of the furniture. The aim was also to produce objects of high aesthetic quality that would be available to everyone. This had also been one of the objectives of the Arts and Crafts movement, promoted by William Morris. But while Morris had rejected industrial production, the artist of the Art Nouveau tried to achieve an alliance between art and industry, taking advantage of modern means of production. However, in

Art Nouveau detail from the Palais Royal metro station in Paris, designed by Hector Guimard. (Jean-Pierre Dalbera)

most cases this resulted in expensive products that could only be bought by an exclusive clientele, although in Germany experiments were carried out that led to the creation of the *Deutscher Werkbund* (German Work Federation) in 1907 and the basis of modern design.

Although the roots of the movement owe a great deal to British ideas, Art Nouveau was never much favored in Great Britain. The movement's major centers were Brussels, Paris, Nancy (an industrial city in Northeast France), Munich, and Vienna, with important developments in Glasgow and Prague as well. The new style manifested itself in different ways according to each nation, but we find some common characteristics, such as the predilection for the use of sinuous and curved lines, decoration derived from or inspired by the study of plants, and the preoccupation with the organic ornamentation of a structure. This focus on vegetal growth was particularly prevalent in France and Belgium, whereas in Scotland, Germany, and Austria a more geometric and abstracted decorative vocabulary was preferred.

In Brussels, the major exponents of Art Nouveau were Victor Horta in architecture, who designed the Hotel Tassel (1891–1892), one of the most well-known buildings of Art Nouveau, and Henry Van de Velde in the decorative arts. Tassel's organic forms greatly influenced French architect Hector Guimard, who designed exuberant buildings in Paris, such as the Castel Béranger (1897–1898), in which the structural parts of the building are organically developed to suit his linear and fluid decoration. In Guimard's design for the Paris Metro Station (1899–1904), the contorted ornamentation, derived from the vegetal and animal world, reaches a totally organic relationship with the iron structure. In Nancy, Emile Gallé specialized in glass production, experimenting with textures and taking inspiration from nature, while Louis Majorelle devoted himself to the creation of furniture.

In Munich, Hermann Obrist produced a celebrated tapestry in 1895 using the motif of the whiplash, which was taken up by August Endell for the facade of the Elvire photography studio (1897–1898), one of the most famous examples of Art Nouveau. In Austria, the Secessionstil turned to a more rigorous and geometrical

search, exemplified by Joseph Olbrich's Secession Building (1898) in Vienna and in the work of Joseph Hoffman and Otto Wagner. Other important exponents of the movement included the highly particular and original Antoni Gaudí in Spain, Charles Rennie Mackintosh in Glasgow, and Alfons Mucha in Prague.

Exhibitions and publications contributed to the international development of the movement, favoring the rapid circulation of new ideas and concepts. *The Studio*, a magazine dealing with painting, sculpture, architecture, furniture, textiles, pottery, and all sorts of crafts, was published in London starting in 1893 and provided a regular insight into all spheres of creation. It was a platform for artists such as Audley Beardsley, whose drawings also appeared in *The Yellow Book*. Other magazines include *L'Art moderne* and *Van Nu en Straks* in Brussels, *Pan* in Berlin, *Ver Sacrum* in Vienna, and *Jugend* in Munich.

The 1900 Exhibition in Paris saw the triumph of Art Nouveau. But the movement's glorious climax rapidly collapsed. By 1902 at the Turin Exhibition, it had already started to look outdated, and by 1908 at the London Exhibition it was almost invisible. In just a few years, Art Nouveau had been eclipsed and was no longer the style of modernity.

American Domestic Architecture

In the first half of the twentieth century, American architects produced some of the most diverse, innovative, and rewarding domestic designs in the nation's history. Accelerated growth in both urban and suburban populations fueled demand for housing. In general, whether working in cities or suburbs, architects and

home builders experimented with new forms of domestic design, incorporated sophisticated technologies, and adapted traditional styles to the changing needs of a self-consciously modern age. The forms and styles of houses in this period of rapid change reflected the range of tastes and social circumstances of the increasingly varied American population.

A rift developed between architects practicing in the so-called academic or traditional styles and those practicing in the newer so-called progressive styles of architecture. However, architects in the period generally adhered to the principle of appropriateness, sometimes also called decorum. Appropriateness suggested that architectural forms should be suited to the functions and purposes, including symbolism, of building programs. Within this framework, architects matched the appropriateness of the style to the social status and function of the building.

Architects were not the only source of design, as pattern books and catalogs provided others. Sears, Roebuck & Co. was the most successful of the mail-order companies that offered prefabricated bungalows and larger single-family houses for sale. In fact, the standardized bungalow—usually a one-story structure with a dominant horizontality—became the preeminent house type in the suburbs.

Colonial Revival was by far the most common stylistic category in domestic architecture from the 1870s through the middle of the twentieth century and even to the present. For many people, the various styles within Colonial Revival were physical manifestations of the entrenched national mythology that saw in the colonial period the existence of a distinctive American culture, although this was inflected by regional differences. In New England, British colonial styles such as the Georgian, characterized by a rigidly symmetrical facade and a central hall, could express a sentimental attachment to the early settlers and provide a symbolic bulwark against the increasing waves of non-Anglo European immigrants. In contrast, various versions of Spanish colonial styles popular in California, Arizona, New Mexico, and Florida took advantage of the warmer climates of those regions and provided an alternative of light, color,

and exoticism to the more conservative East Coast styles.

Many American architects trained at the Parisian *Ecole des Beaux-Arts*, where classicism was the rule, and most schools of architecture in the United States also adopted the *Beaux-Arts* design philosophy. Classicism was thus inculcated among several generations of architects, deeply affecting the appearance of American houses. Among the best-known architects in this mode were David Adler, who worked in the suburbs of Chicago; Philip Shutze in Atlanta; Addison Mizner in Florida; Albert Kahn in Detroit; and Julia Morgan in southern California. Morgan, one of the first successful female architects, is best known for the flamboyant William Randolph Hearst Castle in San Simeon, California, begun in 1920.

At the other end of the spectrum, a number of influential architects rejected traditional styles altogether and promoted a modernist approach that emphasized new materials and building technologies, the architect's free-ranging imagination, and the abandonment of ornament. Modernist architects such as Richard Neutra and Rudolf Schindler designed houses to express the rapid change and technological progress of the modern age. Both had worked for the iconoclastic Frank Lloyd Wright before pursuing their own careers in California, where each built an iconic modernist house for Dr. Philip Lovell. Schindler's Lovell Beach House in Newport Beach and Neutra's Lovell Health House in Los Angeles, both from the 1920s, set a high standard for modernist houses.

Among the technological advances that made domestic living more convenient were central heating, electricity, running water, and natural gas. These services were new luxuries that in a short period of time became household essentials, valued for helping to increase comfort, hygiene, and convenience. Such labor-saving devices reduced the manual labor required for daily tasks and were integral parts of house design.

Indoor bathrooms replaced outdoor privies thanks to running water and improved sewerage. In older houses, closets or small bedrooms were converted into bathrooms. Gas ranges replaced wood-burning stoves, and the telephone

➤ FRANK LLOYD WRIGHT'S DOMESTIC REVOLUTION

Developed in the late 1890s, Frank Lloyd Wright's Prairie Style houses, mostly in and around Chicago, Illinois, incorporated low roofs, horizontal lines, and flowing spaces. Drawing upon both the Arts and Crafts and the Shingle Style of the Gilded Age, the Prairie Style brought Wright international renown. His best-known Prairie design is the Frederick Robie House in Chicago, Illinois, built during 1906–1909. Wright's emphasis on the new social realities of domestic life prompted him to devise a more open and informal house type. The Robie House lies close to the ground, provides deep overhanging eaves, and reduces interior divisions. Emphatically horizontal, the house echoes the flat plains of the Midwest, and by obscuring the entrance and windows it provides a sense of shelter and security that Wright felt was important for domestic life.

In the 1930s Wright designed several houses that launched a new direction in American domestic architecture. Fallingwater, a house for Edgar Kaufmann in rural western Pennsylvania, dramatically cantilevers over a small river and waterfall and encompasses natural rock outcroppings inside. It set a new standard for the relationship

Frederick Robie House in Chicago, designed by Frank Lloyd Wright in 1909. (iStockPhoto.com)

between nature and architecture. Wright's Usonian Houses of the 1930s were an attempt to create an affordable house type for all Americans. The Usonians were designed as part of a new suburban landscape called Broadacre City, Wright's concept of decentralized land development that would be largely realized (without Wright's help) in the postwar suburbs.

—Paul Ranogajec

became a standard feature of middle-class respectability. By the 1920s, most Americans had come to expect a large amount of convenience in their domestic arrangements that would have been unthinkable just one generation earlier. This era, then, marks the birth of the modern house.

At the opposite end of the building scale, skyscrapers were used increasingly for domestic accommodations. Invented in the nineteenth century following advances in steel construction, mechanical elevators, and fire safety measures, skyscrapers were first considered suitable only for commercial structures. Early apartment towers such as Henry Hardenbergh's Dakota Apartments in New York paved the way for their use as urban domestic accommodations. Most high-rise apartment buildings were designed in traditional styles until 1925, when Art Deco became a popular alternative. Its streamlined forms and geometric patterns often emphasized soar-

ing vertical lines to dramatize high-rise living. Among the most celebrated Art Deco domestic buildings are those in Miami Beach, Florida, characterized by their warm colors, abstract surface patterns, and rounded corners.

After World War I there was an important shift in housing patterns. Suburbs expanded even as cities reached their maximum size. City populations were fueled by continuing high levels of immigration, but the suburbs were populated by middle-class residents newly mobilized to leave the city thanks to the widespread acceptance of the automobile. The architecture and settlement patterns of these new suburbs were conditioned by zoning and restrictive covenants. Zoning set rules for the types of functions that the land could accommodate, usually separating residences from commercial and industrial areas, while restrictive covenants were used to promote racial and economic homogeneity, excluding minorities and the poor. Wielding tremendous

power, developers and real estate associations often controlled the exterior appearance of the houses themselves.

Suburban development radically changed the American landscape. The federal government influenced this change by means of its active role in suburban planning starting during the Great Depression. Greenbelt, Maryland, begun in 1935, was one of several new suburban towns built to provide low-cost housing close to industrial work. On the side of private enterprise, the model suburb of Radburn, New Jersey, was laid out in 1928 by reform-minded urban planners as a small self-sufficient community. In these and most other suburbs, cul-de-sacs lined by houses were separated from major traffic arteries, promoting the ideal of an isolated, secure enclave that has been a dominant theme of American suburban life ever since.

Toward Functionalism

The equation of function with beauty owes much to the related classical ideals of utility, beauty, and firmness proposed by the first-century BCE architect Marcus Vitruvius Pollio. The term “functionalism,” however, emerged in the mid-nineteenth century to represent the belief that

the parts of a whole, be it a sculptural form or a building form, should be essential to that whole. In architecture, with which functionalism is most often associated, this parts-to-whole relationship was translated to mean that the attendant parts of a building should contribute to the overall function of that building. In other words, nothing should be wasted, and everything must be meaningful to the total enterprise.

In the 1840s and 1850s, the quality of being functional meant that a form possessed fitness, which was theorized in various disciplines and by many different kinds of scholars, including the essayist Ralph Waldo Emerson (1803–1882) and the sociologist Émile Durkheim (1858–1917). The American sculptor Horatio Greenough (1805–1852) was the first to think about form and function as mutually dependent elements of architecture and space. In his 1843 essay “American Architecture,” he succinctly noted that banks should have the “physiognomy of a bank,” meaning that if the building operates as a bank, it should be laid out to optimally work that way.

It was the Chicago architect Louis Sullivan (1856–1924), however, who famously expanded this idea in the now-often misquoted dictum that form follows function. In his landmark 1896 essay “The Tall Office Building Artistically Considered,” he proposed that the way a building is articulated—that is, designed and built—should reflect that building’s purpose. The essay prescribed a form for the tall office building, the precursor to the modern skyscraper, as first having a base that would serve pedestrian purposes at ground level, such as retail space, by offering large display windows. Above the base, a series of identical floors should contain a honeycomb of offices, likening the efficiency required of office workers to the kind achieved by bees. Crowning the tall office building was an attic level that should contain the mechanical equipment required by elevators and, more importantly, distinguish itself as a mechanical space on the outside. That “form should ever follow function,” Sullivan’s actual words, meant that the purpose of a building (tall or otherwise) should be evident from its appearance.

Functionalism was also a moral argument that architecture should present itself honestly. Honesty, transparency, and truth became synon-

ymous terms that were linked by new uses for old materials in the second half of the nineteenth century. Glass in great quantities became ubiquitous in architecture, as it was considered an inherently honest material for its transparency even if in reality its reflective qualities sometimes defeated that altruistic notion. In tall buildings, glass could be used to create curtain walls, or walls that do not carry any structural loads and are free to be as thin and light as possible. One of the beneficial effects of this, of course, was that interior spaces could be far brighter and appear lighter than the typical Victorian room of the period, a condition that would influence the way that these spaces were arranged in plan.

The thing that made this use of glass possible came in the form of advances in structural systems, which had made a quantum leap in 1851 with Joseph Paxton and William Cubitt's Crystal Palace in London, built for the Great Exhibition of that year. Before midcentury, masonry construction was the principal mode for building. In it, brick, stone, marble, granite, and other materials are arranged and bound by mortar. The Crystal Palace, on the other hand, was composed entirely of wrought iron and glass and, because of the lightness and versatility of these materials, spanned more than 1,800 feet in length (equivalent to five football fields) and had a height of more than 400 feet (120 meters). To achieve those dimensions, the base of a traditional masonry building would have to be several feet thick in order to support the weight of the upper stories. Paxton and Cubitt's hall, on the other hand, was only as thick as a panel of glass from top to bottom.

If functionalism was aligned with modernism, a fundamental part of that relationship was represented by the ways that iron and glass could reduce the time and labor that construction required. Iron beams and glass windows could be produced off-site, transported, and assembled relatively easily, unlike the labor-intensive processes involved in masonry construction. Iron and glass buildings represented an efficient process of construction and an economy of means: the smallest amount of raw material used to create the greatest product. Steel would later be more widely used for its superior strength, but

the material spirit of functionalism, that less is more, remained.

"Less is more," often attributed to the German architect Ludwig Mies van der Rohe (1886–1969) in the early twentieth century, can be traced to the English poet Robert Browning (1812–1889), who explored the same minimalist position of Emerson, Durkheim, and Greenough that any idea, work, or form can be paired down to its essential elements. Just as functionalism was a moral argument about architecture, minimalism was a moral argument about the visual arts. Anything that was extraneous, unnecessary, or ornamental was unmodern and in some ways regressive. The Austrian architect Adolf Loos (1870–1933), in his 1913 essay "Ornament and Crime," castigated the flourishes and organic gestures of Art Nouveau and claimed that ornament was primitive and therefore immoral. His example was the practice of the so-called uncivilized Papuan to wantonly tattoo himself, in stark contrast to the modern man for whom such acts were thought to be criminal.

Industrialization, rapid urban growth, and a dearth of sanitary practices plagued many European and American cities for decades leading up to the turn of the century. Loos's position was extreme, but it represents the polemical nature of functionalism in modern architecture: its practitioners can and should create a more civilized society and improve the living and working conditions of everyone. If only things and people worked efficiently and properly, society could function as a whole, and the modern *zeitgeist* could be realized.

■ Introduction: Performing Arts

The period from 1900 to 1945 highlighted wrenching changes and experimentation in the performing arts worldwide. Simultaneously, mass culture was shaping a new popular art, standardized and distributed en masse via print and new electronic media. During this period, cinema came of age as the primary mode worldwide for popular storytelling: as it progressed as an art form and industry, simple travelogues gave way to elaborate narratives that included sophisticated editing techniques, sound, color, and the resources of production studios.

In music, modernists such as Arnold Schoenberg rejected inherited traditions, including classical Western harmony, with the development of his 12-tone row, while innovators such as Charles Ives created new pastiches that included atonal harmonies and quotations from popular music. A new era of sound was hinted at as well with

Soviet inventor Leon Theremin's development of the first electronic synthesizer, the Theremin, introduced to the West amid much acclaim in 1927. On the popular level, jazz rhythms infiltrated light popular music in the 1920s and came of age with the big band swing of the 1930s and 1940s in orchestras including those of Duke Ellington, Count Basie, and Benny Goodman. The introduction of the microphone also shaped a new singing style, that of the smooth crooner such as Bing Crosby, who no longer needed to overemote and shout to be heard in all corners of an auditorium, as had Al Jolson.

Important developments in theater include Constantin Stanislavski's founding of the Moscow Art Theatre in 1897 and his work in developing what later became known as the method school of acting, applied with great effect to the plays of Anton Chekhov. In the early twentieth century, George Bernard Shaw developed his argument-based dramas. Following World War I, expressionist plays explored the dehumanization of the machine age, such as Czech author Karl Capek's *R.U.R. (Robert's United Robots)* and Elmer Rice's *The Adding Machine*, whose hero was named "Mr. Zero." In the same period, Surrealism was reflected on the stage in such works as Guillaume Apollinaire's *The Breasts of Tiresias*, while Luigi Pirandello offered his metadrama *Six Characters in Search of an Author* (1921).

Until the Stalinist regime solidified, the Soviet Union was a mecca for modernist arts experiments. Vsevolod Meierhold, a Stanislavsky disciple, applied his theory of "bio-mechanics" to acting and created an experimental theater that broke free of many of drama's realist conventions; many of his Soviet-sponsored productions toured throughout Europe in the 1920s. German playwright Bertolt Brecht's Marxist-based theories of theater rejected the "fourth wall" and sought to strip away the glamour of theater to instead reveal the craft as a product of labor. Brecht's theater, with its frequent satire of capitalism (*Rise and Fall of the City of Mahoganny*) was forged as a pedagogical tool to help audiences recognize the contradictions built into the existing world

➤ RADIO AND JAZZ

Nightclubs, speakeasies, and the new radio transmission technology all promoted the early popularity of jazz. Radio transmissions of music allowed jazz to become a mainstay in the airwaves and increase its popularity outside of the urban centers with which jazz is typically associated. Both recorded and live music were played over the radio, drawing much attention from radio listeners as the medium became ever more popular by virtue of its novelty. However, while jazz was identified with mostly black musicians, over the radio it was rare to hear or listen to black musicians, as most jazz was played or sung by white musicians. The decade's greatest African American vocalists, most notably Louis Armstrong, Bessie Smith, Ma Rainey, and Florence Mills, were seldom heard on radio broadcasts. The hundreds of other black artists who recorded on "race record" labels in the 1920s were also not played on the radio. While many white American radio broadcasters and aficionados did appreciate and admire black musical styles, they still retained many of the existing racial prejudices of the time.

—Abraham O. Mendoza

order. In the newly formed Soviet Union, agitprop (“agitation and propaganda”) theater was born, a movable theater meant to energize the masses, provide the latest news, and coach them in revolutionary principles via broad strokes and simple sets and props. In the United States, serious drama came of age with the plays of Eugene O’Neill of the 1920s, while the 1930s was a period of great ferment; a proletarian aesthetic emerged in plays such as Clifford Odets *Waiting for Lefty*. The U.S. government, as part of the New Deal’s aid to the arts, from 1935 to 1939 sponsored the Federal Theater Project that included in its offerings circus and vaudeville units, living newspapers such as the pageant “Power, A Thrilling Dramatization of Modern Industry,” and experiments such as Orson Welles’s version of *Macbeth*, soon known as *Voodoo Macbeth*, developed with the project’s Negro Theatre Unit.

On the popular level, vaudeville and music halls—with their standardized variety offerings—remained a popular art form, with well-established circuits in the United States and Europe and elsewhere until the 1930s. Risqué burlesque entertainments had also developed with their own circuits, while the more upscale Ziegfeld’s Follies combined “leg shows” with sophisticated stage sets, music, choreography, and Ziegfeld’s promised goal of “glorifying the American girl.” An offshoot of European operetta, large Broadway musicals were also undergoing a Golden Age in the United States, as Tin Pan Alley composers crafted shows with unified themes throughout the song lyrics, an approach that culminated in Rodgers and Hammerstein’s *Oklahoma* (1943).

—Fred Nadis

Atonal Musical Theory

The term “atonal music” refers to any music composed without a tonal center and outside of the major- and minor-scale system. While tonal music is based on 7-note scales wherein each tone or triad has a specific function, atonal music has all 12 notes of the chromatic scale available; they can be combined independent of the contextual relationship that triads, keys, and scales have in tonal music. “Atonal” is an imper-

fect term for such music, as it connotes the absence of tonal harmony without describing the resulting music. While initially rejected by the composer Arnold Schoenberg, a pioneer of atonal music, and employed by critics as an epithet, the term “atonal” has established itself. Some scholars limit the term “atonal” to music written before the advent of the 12-tone method (ca. 1923); others find it lacking because it does not allow for distinction between “free” atonality and the 12-tone, or dodecaphonic, compositions that followed. The 12-tone method, developed by Schoenberg, applies a system to atonal composition; dodecaphonic works are structured by a series, or tone row, of all 12 notes of the chromatic scale in a set order determined by the composer and are thus examples of serialism in composition. Free atonality and dodecaphony represent distinctive phases of new musical directions in composition and theory, and both should be included in a cultural-historical consideration of atonal music.

The roots of atonal music extend to Franz Liszt in the late 1870s and Claude Debussy in the 1890s. Their chromatic expansion of harmony was taken further by Schoenberg in the early twentieth century. He pursued what he termed the “liberation of dissonance” by setting aside the rules of harmony and employing the full range of harmonic combinations allowed by the full 12 notes of the chromatic scale. The Second Viennese School, which refers to Schoenberg and his students, particularly Alban Berg and Anton Webern, are thus often considered the founders of atonal music.

Schoenberg began to compose atonal music in 1908, the same year in which composers as diverse as Bela Bartok, Aleksandr Scriabin, and Charles Ives were working on compositions that also indulged dissonance and employed only a loose sense of key. Late-nineteenth-century European musical culture was marked by a divide between adherents of Richard Wagner’s *Zukunftsmusik*, or music of the future, and those who favored the traditionalism represented by Johannes Brahms. Composers of the Second Viennese School did not think that the two factions were irreconcilable. Wagner moved away from traditional tonality and employed chromaticism to express revolutionary sentiments of a political

► **TIMELINE OF SELECTED ATONAL OR 12-TONE COMPOSITIONS OF ARNOLD SCHOENBERG, ALBAN BERG, AND ANTON WEBERN**

- 1908–1909—Schoenberg composes *Das Buch der hängenden Gärten*, song cycle of poems by Stefan George.
- 1909—Schoenberg composes *Five Pieces for Orchestra* as well as *Erwartung*, a one-act opera that is first performed in 1924.
- 1909—Webern composes *Six Pieces for Orchestra*, op. 6.
- 1910—Berg composes *String Quartet*, op. 3.
- 1910–1913—Schoenberg composes *Die glückliche Hand*, a drama with music that is first performed in 1924.
- 1912—Schoenberg composes *Pierrot Lunaire*, a setting of Otto Erich Hartleben's translation of Albert Giraud's poetic cycle.
- 1913—Webern composes *Six Bagatelles for String Quartet*, op. 9.
- 1914—Webern composes *Three Little Pieces for Cello and Piano*, op. 11.
- 1914–1922—Berg composes *Wozzeck*, an opera, first performed in 1925.
- 1925–1926—Berg composes *Lyric Suite* for string quartet.
- 1928—Webern composes *Symphony*, op. 21.
- 1929–1935—Berg composes *Lulu*, an opera, first performed in 1937.
- 1930–1932—Schoenberg composes the unfinished opera *Moses und Aron*.
- 1936—Schoenberg composes *Concerto for Violin and Orchestra*, op. 36.
- 1938—Webern composes *String Quartet*, op. 28.
- 1947—Schoenberg composes *A Survivor from Warsaw* for narrator, men's chorus, and orchestra, op. 46.

—Anthony Cantor

and sexual as well as musical nature. The destabilization of tonality by dissonance and chromatic tones is of a piece with the assault on laws and hierarchy in art and politics that led nineteenth-century cultural observers to view themselves as living in a “century of movement,” as described by Carl Schorske. The sensation of uprootedness that resulted from the undermining of the tonal center is also reflected in the art and literature of that time and place. Schoen-

berg described himself as seeking “complete liberation . . . from all symbols of cohesion and of logic,” just as artists and intellectuals such as Gustav Klimt and Sigmund Freud perceived a world in flux, unmoored from old verities. While Wagner's dissonance was tempered by familiar harmonies, composers of the Second Viennese School completely replaced old harmonies with new ones; Schoenberg in particular was wont to employ the dissonant intervals of the minor ninth and major seventh. As Webern later commented, “We broke [tonality's] neck.”

Schoenberg described his compositions as the necessary outcome of a historical process. His analysis of tonal harmony in *Harmonielehre* (1911), steeped in the discourses of social Darwinism and racial pseudoscience that permeated intellectual endeavor, saw tonality as a formerly logical, ethical, and healthy musical language that had degenerated; the composer required purity and asceticism. Schoenberg spoke about tonality in the same language that his contemporaries Wagner and Otto Weininger employed to describe the supposedly nefarious influence of Jews in Austro-German culture. Schoenberg, like many leading figures of Wiener Moderne, or Viennese modernity, was Jewish. Jews had acclimated well to the upheavals of modernity; they were well represented among Vienna's educated middle classes but hardly monolithic in their philosophies and politics. Alex Ross suggests that the “weird undercurrent” of pseudo-scientific racism in *Harmonielehre* and Schoenberg's 1898 conversion to Lutheranism were both efforts undertaken by Schoenberg to separate himself from Jewish stereotypes. With the rise of anti-Semitism as an unavoidable political and cultural reality in Austria and Germany, Schoenberg's relationship to his Jewishness evolved; by 1933 he had embraced his Jewish identity and Jewish faith.

The break with tonality should not be regarded as a musical development abstracted from its cultural moment. The Second Viennese School was a constituent element of the political, philosophical, and aesthetic innovations that arose in Vienna from the turn of the twentieth century through World War II. Schoenberg, in railing against the aesthetic values of beauty and comfort, heeded the call of his friend, the

architect Adolf Loos, that art's purpose was "to shake us out of our complacency and comfort." Sometimes called critical modernists, these artists revolted against the cult of beauty, which they regarded as a lie that masked the failures of their society to realize its liberal, tolerant promises. During 1912–1914 Schoenberg worked on an ultimately unfinished symphony that would have dramatized the death of the bourgeois God. Schoenberg's opera *Moses und Aron* (1926–1932), based on a tone-row, set Truth and Beauty in opposition, cast art as a corruptor of truth, and indicted those who trusted in art and beauty.

The Second Viennese School was also influenced by the critic Karl Kraus, who campaigned against kitsch in his periodical *Die Fackel* (*The Torch*). Berg was an enthusiastic attendee at Kraus's lectures, and Webern imparted Kraus's convictions about the dangers of even minor linguistic errors to his students. The protagonist of the novel *Doctor Faustus* (1947) by Thomas Mann, also an admirer of Kraus, is depicted as having invented the 12-tone method; the novel explores the intellectualism of modern art, the rise of irrationalism, and the roots of fascism. Though Schoenberg and his students had only passing contact with Freud, psychoanalytic explorations are apparent in works such as Schoenberg's opera *Erwartung* (1909). These are but a few of the ways in which atonal music is connected to cultural and intellectual life.

Schoenberg's hope that one day people would whistle his tunes has not come to pass. Still, atonal music continues to exert influence even on those composers who do not produce atonal or dodecaphonic compositions. The serialism of 12 tones that Berg and Webern learned from Schoenberg was developed after World War II by composers such as Milton Babbitt, Pierre Boulez, and Karlheinz Stockhausen into "integral" or "total" serialism, the serialism of musical elements other than pitch, such as rhythm, tempo, and dynamics.

Music and Nationalism

Nationalism emerged as a way of thinking that included a strong patriotic pride for one's homeland. Musical nationalism reflected the conscious efforts of composers to identify their tradition. The recovery of a country's music—songs, ballads, folk melodies—was a central part of national revival. A sense of national heritage and pride was drawn from the oral culture, the music of the folk, that was held to express unique qualities of each nation. As the emergence of the nation-state as a territory defined by language, music, a history, and common culture came to be equated with progress, music intertwined with these national aspirations. Composers consciously turned to folk idioms, hoping to recover the spirit of the nation. Utilizing the resources of folk dance and folk song provided a means to express the native life of the people.

The twentieth century began with further assertions of nineteenth-century nationalism, during which time political fervor shot through Europe and composers adopted the rhythms and melodic attributes of folk song. *Finlandia* (1900), composed by Jean Sibelius (1865–1957), espoused nationalism in Finland at a time when that nation was controlled by Russia. Edvard Grieg (1843–1907), in Norway, used folk song materials and composed on national themes. Bela Bartok (1881–1945) in Hungary and Carl Nielsen (1865–1931) in Denmark mined the folk resources of their countries. Nationalism appeared in the music hall in England during the

Boer War. When Edward Elgar's *Pomp and Circumstance* appeared in 1902, a lyric was set to it that spoke of Britain as a "Land of Hope and Glory." In 1916 Hubert Parry (1848–1918) set William Blake's *Jerusalem* as a nationalistic ode. Later, Ralph Vaughan Williams (1872–1958) recalled English folk songs as central to the English nation, reaching back to the Elizabethan era for some of these.

In the twentieth century, nationalism is often considered discontinuous with modernism. The National Socialists in Germany suppressed modernist composition. Russian composers were required to embrace Soviet state-sponsored themes for music. Whereas the modernist Sergei Prokofiev (1891–1953) invented his own style, Dmitri Shostakovich (1906–1975), seeking individuality, often blended with the new Soviet style.

In the United States, Charles Ives (1874–1954) and Aaron Copland (1900–1990) developed modernist compositions in connection with texts that reflected national images. For Ives, there was the New England landscape. For Copland, who drew upon American folk texts and Native American backgrounds, there was the cowboy, the Native American, and the American vistas suggested by John Steinbeck's *The Red Pony* (1933). Several attempts were made to point to jazz as indigenous to America. Among these was William Grant Still's *Afro-America Symphony* (1930), using jazz as America's music.

Latin American music is often markedly nationalistic and represents diverse traditions. Traditional music is reclaimed, some say "reinvented," in the interest of expressing the self and culture. Typical of this in Mexico is Jaime Nuno's Mexican national anthem of 1854 and mariachi music. In Central America, Carlos Chavez (1899–1978) composed on Indian themes, and his students built upon folklore. As Latin American people sought to define the nation apart from colonial influences, they drew upon music and other cultural expressions. There were many African influences upon Caribbean music and upon Portuguese-speaking Brazilian music. In Brazil, Heitor Villa-Lobos (1887–1959) developed a considerable output of chamber, choral, and symphonic works, filled with Brazilian rhythms. Calypso, reggae, ska, and other music forms emerged from the islands, often with lyrics that embodied political

protest. In Haiti, French traditions were gradually replaced by an African-inspired musical culture of percussion. When competing colonial regimes sought political control of the Caribbean, colonial conditions prompted the development of carnival and calypso in Trinidad. In Trinidad festivals there emerged a repertoire of song and dance, including *calinda*, *jboba*, and *bamboula*. In Cuba, Eduardo Sanchez de Fuentes (1874–1944), Alejandro García Caturla (1906–1940), and Amadeo Roldán (1900–1939) expressed the Right, Center, and Left of politics, respectively, with Roldán absorbing Black forms in his music. Ernesto Lecuona y Casado (1895–1963) composed *Malaguena* and *Siboney*, which are among the most memorable of Latin American compositions.

Expressionism in the Performing Arts

Shocked at the devastation caused by World War I, artists saw in German Expressionism a means to come to terms with the social and political turmoil as well as an opportunity to sound the call for social renewal. Seeking to give visual form to inner urges and desires, Expressionists revolted against bourgeois morality, which, with its strict social codes, they believed constrained the authenticity and spontaneity of expression. World War I initially seemed to fulfill their desire for social purification. By 1916, however, the true nature of the war had become evident, and with the abdication of Kaiser Wilhelm in 1918, the Expressionists redirected their aspirations for a new and reformed society to the Weimar Republic. Their hopes were disappointed once again by the problems plaguing the nascent gov-

► THE CABINET OF DOCTOR CALIGARI

The Cabinet of Doctor Caligari premiered in German movie theaters in February 1920. In the movie, Doctor Caligari has a stand at a carnival featuring a somnambulist named Cesare. Using his powers of hypnosis over Cesare, Caligari has him commit murders in the town. The two central characters, Francis and Jane, begin to investigate, and this leads to Caligari's orders to Cesare to kill Jane. But captivated by her beauty, Cesare is unable to kill her and kidnaps her instead, only to fall to his death while pursued by the townspeople. Francis then discovers that Caligari is actually the director of the local insane asylum. When confronted with Cesare's corpse, Caligari breaks down and is imprisoned in his own asylum. However, what makes this film so distinctive is the framing device inserted around the narrative by the director Robert Wiene. The opening scene presents the body of the story as a flashback narrated by Francis. However, when the flashback ends, it reveals a surprising twist: Francis, Cesare, and Jane are all shown as inmates of the asylum with Caligari as the benevolent director. The story was in fact one of Francis's delusions.

ernment, and the political element of Expressionism never managed to engender the transformation of society it desired.

Some of the earliest Expressionist plays—including Wassily Kandinsky's *Yellow Sound* (1909) and Oskar Kokoscha's *Murderer, the Hope of Women* (1909)—were written before the war by painters and sculptors who were also interested in theater. These artists translated characteristics of Expressionist painting and prints for the theater, notably the use of stylized and unnatural figures and the extreme simplification of form. *Yellow Sound*, for example, had no dialogue, and the music, lighting, and set designs were intended to construct abstract pictures rather than realistic scenes. *Murderer, the Hope of Women* was even more antinaturalistic; its characters were reduced to emblematic types, such as The Man and The Woman, while both the speech and gestures of the actors were deliberately exaggerated.

This move away from mimetic representation toward a cultivated artificiality would become characteristic of Expressionist theater as it flourished from 1916 through the early 1920s. Simplified and often abstract set designs replaced the elaborate and realistic ones of previous years. The plot progressed episodically with little regard for causality or character development. Dialogue was declaimed rather than naturalistically acted and was accompanied by equally spastic and unnatural gestures, while directors enhanced the emotional intensity of the play through their use of lighting to create stark contrasts between light and dark. The difference between Expressionist theater and the more conventional naturalistic approach is amply demonstrated in Leopold Jessner's production of *William Tell* (1919). Jessner eliminated all references to Switzerland, highlighted the difference between the good and bad characters through the use of white and black costumes, and limited the set design to a series of

bridges, ramps, and stairs with an abstract mountain range in the background. But if Expressionist actors and directors embraced an obvious artificiality in the production, this was never taken to include the expression of emotion, which was to remain intense and authentic throughout. The ecstatic performance of the actors on stage and their reduction of movement and speech were a result of their search for a new language of the body capable of communicating a purity of expression.

The Expressionist reaction against bourgeois society and established authority often took the form of a dramatic struggle pitting sons against fathers, with the father representing the strict German code of social and moral taboos. In Walter Hansencleaver's *The Son* (1918), for example, the son believes that by shooting his father he can save humanity. When the son confronts his father with a pistol in hand, the father dies of a heart attack, and the play ends with the son striding triumphantly over his father's corpse into his new future. This patricide is not only antiauthoritarian but also embodies Germany's anxiety over its history and its attempts to liberate itself from the past. In the place of the father the Expressionists envisioned the new man, an enlightened figure capable of leading the masses because of his power of expression, as in Ernst Toller's *The Transformation* (1917/1918), in which the protagonist voluntarily enlists in the military only to evolve into an opponent of war and ultimately a revolutionary leader.

The prevalence of Expressionism in art and theater facilitated its entrance into cinema, heralded by the premiere of *The Cabinet of Doctor Caligari* in 1920. With its dramatic lighting and distorted sets and the inclusion of actors Werner Krauss and Conrad Veidt, who had both starred in Expressionist plays, *Caligari* translated features of Expressionist art and theater into film. Directed by Robert Wiene and based on a screenplay by Hans Janowitz and Carl Mayer, the film presented a horror story with plot extremes and twists that delighted the public. The brevity and stylized lettering of the original titles (although in the English version the clipped and telegraphic titles have been lengthened into narrative description) added to the heavy shadows, slanting doors, curved walls, and angled win-

dows of the scenery and echo the distortions and extremes of the characters and plot.

Although the Expressionist impulse in the other arts had largely waned by the time *Caligari* appeared, the enormous success of the film engendered a vogue for Expressionist cinema in the early 1920s. Some, such as Karl Heinz Martin's adaptation of the Georg Kaiser drama *From Morn to Midnight* (1920), were Expressionist in both form and content, with abstract sets and stylized acting in addition to an episodic plot structure. Far more common, however, were films, ranging from *Nosferatu* (1922) to *Metropolis* (1927), that utilized Expressionist sets while drawing their themes, characters, and imagery from romantic tales and other literature of the period. For a while, even some films that exhibited no characteristics of the new cinematic style went so far as to have Expressionist advertising, seeking to capitalize upon the "Caligari mania." In part, this was a means of making cinema a more respectable medium. By associating itself with an avant-garde movement, cinema presented itself as a legitimate cultural attraction on par with the other arts. Yet it also shows the degree to which Expressionism as a style had become divorced from the politics of its earlier years.

The Jazz Age

The Jazz Age, a term coined by world-renowned American author F. Scott Fitzgerald, describes the period from the end of World War I to the emergence of the Great Depression. The Roaring Twenties, as this period is also known, was

characterized by the waning of traditional values as they were challenged by new cultural trends in the United States and Europe, among them jazz music. From the early twentieth century and into the 1920s, the terms “ragtime” and “jazz” were often used synonymously, and much of what was labeled jazz was actually popular music typically in ragtime form or other syncopated musical styles.

Jazz combined black West African folk music forms—developed in North America for decades during the eras of slavery and postemancipation—with European musical influences, much of it filtered through the popular song-writing industry of Tin Pan Alley in New York, whose composers sought to re-create a syncopated ragtime sound. The popularity of jazz spread as the music emerged as a key aspect of the Harlem Renaissance, a flowering of interest in African American arts and culture in the 1920s in New York City. Audiences attributed freedom, spontaneity, and adventure—associated with myriad cultural and societal changes occurring in the 1920s—to the jazz sound.

The 1920s was a decade of profound social changes not only in the United States but also in much of Europe. The atrocities of World War I had shaken the social and political foundations of the Victorian Era and exposed the younger generations to the horrors of the trenches and the perceived corrupt values of the older generation. Young men, who returned from the front lines where they were forced to stare death in the face on a daily basis, were eager to enjoy what was left of their lives. Many young women, having been exposed to the freedoms offered by war-industry employment, were reluctant to return to the Victorian propriety expected by their elders. Two additional trends contributing to the societal changes were the rise of a consumer-oriented economy and new forms of mass entertainment, which triggered what historian Frederick Lewis Allen termed a “revolution in morals and manners.” In the United States, Prohibition legislation inadvertently created the ubiquitous culture of the speakeasy, where both men and women enjoyed illegal moonshine and cocktails and danced and listened to new musical styles.

In Europe young people of both genders, disenchanted with the cultural institutions of their

➤ DJANGO REINHARDT AND GYPSY JAZZ

Django Reinhardt was one of the first and most prominent European jazz musicians and one of the most acclaimed jazz guitarists of all time. Born in Belgium in 1910, Reinhardt was the son of a circus clown and spent much of his life in gypsy caravans in and around Paris. Heavily influenced by Louis Armstrong and other American jazz musicians, Reinhardt managed to successfully fuse American-style jazz with traditional European folk elements. Despite losing the use of two fingers and a thumb on his left hand in a fire when he was 18 years old, he played lead guitar for one of the first all-string jazz bands in the world, the Quintette du Hot Club de France. This group pioneered Gypsy jazz and popularized the new genre throughout Europe and the United States. Reinhardt was so popular in Europe that he was able to continue playing his music during World War II in occupied France. This is an incredible testament to his popularity considering his Gypsy heritage, his defiance of authority by refusing to perform in front of flags bearing a swastika, and the fact that jazz was looked down upon as “black” music by the Nazi regime. In 1943 Reinhardt refused an invitation to go on a tour of Nazi army bases across Europe; instead he attempted to escape to neutral Switzerland. He was captured en route, but fortunately for Reinhardt his captors were jazz fans. Instead of sending him to a concentration camp, which was the fate of so many other Gypsies during the war, Reinhardt was merely returned to Paris. Even long after his death in 1953 from a brain hemorrhage, Reinhardt continues to have a large following of music aficionados and jazz fans the world over.

parents that had sent them and their deceased peers off to war, embraced their newfound liberation, and they pursued a more unconstrained lifestyle amid the political and social tumult that shook postwar European society. During the 1920s sexual morality, prescribed gender roles, fashion, and even hairstyles (such as the notorious bob) changed dramatically. Many Americans and Europeans saw such change, accompanied

American composer, bandleader, and pianist Duke Ellington at the Cotton Club in New York City, with the Cotton Club Orchestra, 1930. (Frank Driggs Collection/Archive Photos/Getty Images)

by commercial culture and new entertainment forms, as a radical break with a recent Victorian or even Puritan past. This was the context in which jazz emerged as a popular form of music, representative of the break with the past and an embrace of the revolutionary.

Ragtime, the direct predecessor of jazz, was a new music that developed largely among African American musicians in the saloons along the Mississippi River in the American South, most notably in New Orleans, during the post-Civil War period. Many of the innovations attributed to jazz emerged from musicians in the early twentieth century in New Orleans. In the early 1920s there was a rapid migration of jazz artists to Chicago following the so-called Great Migration of many American blacks from the South to northern cities in pursuit of greater economic and social opportunities. This migration brought about yet another change in jazz style, later acknowledged as the Chicago style. This innovation in jazz focused on the soloist and also added the use of the saxophone. The saxophone had a more complex and textured sound, thereby contributing significantly to this developing style, along with the cornet. From Chicago, jazz began to make its way to New York City, particularly to Harlem, and to other major U.S. cities such as

San Francisco, Los Angeles, and St. Louis. Jazz in the Dixieland and early swing form as popularized by King Oliver, Louis Armstrong, and later Duke Ellington, Fletcher Henderson, and others was spreading nationally and by the mid-1930s became America's popular music with the aid of numerous touring swing big bands, radio coverage, and the recording industry.

Postwar Harlem was in the midst of a cultural movement known as the Harlem Renaissance during which American black culture embraced literary, musical, and artistic endeavors. In Harlem jazz music was extremely popular and influential, drawing white audiences as well as local black aficionados. Among the innovations to jazz from Harlem was the integration of the piano into musical pieces, often marked by intricate and complex chords. Many nightclubs and speakeasies drew large crowds eager to listen to jazz during this period of its evolution. Notable U.S. jazz artists such as Louis Armstrong, Bix Beiderbecke, and Duke Ellington emerged out of the 1920s jazz scene. The jazz scene in many American cities also created close contact between white and black patrons of nightclubs and speakeasies, much to the shock of older generations. While these interactions did not lead to the loosening of the racial conflict in the 1920s United States, it did mark growing white American regard and outright admiration for black American cultural forms. The Cotton Club was a famous Harlem nightclub that featured many of the more notable black entertainers of the time such as Duke Ellington, Cab Calloway, Ella Fitzgerald, Louis Armstrong, Billie Holiday, and Ethel Waters. However, it denied entry to blacks. In its heyday it was a celebrity hotspot in Harlem frequented by celebrities such as Al Jolson, Mae West, Irving Berlin, and New York mayor Jimmy Walker, among others.

Jazz, particularly as it flowered into the Big Band sound of the 1930s and 1940s, was an influential addition to music during this interwar period in many urban centers around the world. In addition to the above-noted U.S. cities, Paris also became a significant center of jazz music, as it had always been hospitable to artistic innovations and the avant-garde. Paris also had a significant black population of U.S. soldiers who refused to return to Jim Crow America, having

enjoyed life in France during World War I. Many of these Parisian blacks, familiar with innovations in jazz back in the United States, adopted the style and created their own scene in Paris, drawing large crowds of local Parisians and American expatriates. Nightclubs in Berlin, London, Tokyo, and Shanghai also promoted jazz music, illustrating its global reach.

Blues

The roots of blues music stretch back before slavery to Africa and Europe; however, the blues music that we now know germinated during the 1890s and flowered as a musical form in the first decade of the twentieth century. This new music rose from the black farms and towns of the American South during a time when lynching was on the rise, segregationist Jim Crow laws and disfranchisement were spreading throughout the region, and the economic and social position of black Americans as a permanent underclass was being viewed as acceptable.

The blues derived from the European folk ballad, but its sound and feel came out of the cotton and corn fields of the rural South, a descendent of the arwhoollie, or field holler, the song of the plow hand working the land. It was a music free and forceful in its melody, lyrics, and expression. By the turn of the twentieth century, gospel and church music in the form of black hymns and spirituals had also channeled into secular ragtime, jazz, and blues. Each is a uniquely American musical form because it combines European and African musical traditions.

In 1912 the sheet music for W. C. Handy's "The Memphis Blues" was first published along with three other songs with the word "blues" in

Blind Lemon Jefferson, American country bluesman, singer, and guitarist. (Hulton Archive/Getty Images)

their titles. In 1920 the first blues record was released: Mamie Smith's "Crazy Blues" was a tremendous success, selling 75,000 copies the first month and a million copies the first year. By 1927 more than 500 blues and gospel recordings were being released in the United States, most of them featuring black female vocalists. Vaudeville blues stars, most of them women, were recorded throughout the 1920s, often accompanied by a small jazz band. Blues women of the 1920s, Gertrude "Ma" Rainey and Bessie Smith most prominently, appeared in minstrel and medicine shows, in circuses, and on vaudeville stages across the South, often singing the blues along with a mix of other types of folk and popular music. In fact, most early blues musicians played a range of songs, including ragtime, ballads, spirituals, and dance tunes. Likewise, many jazz bands relied heavily on blues forms. Talent scouts scoured the South, and in 1926 new records by Blind Lemon Jefferson began a wave of folk blues that extended through the early 1930s. The country blues was sung by mostly male singers, often accompanied

> ROBERT JOHNSON (1911–1938)

In life, Robert Johnson was an obscure musician playing and singing in the rural Mississippi Delta; in death, he became a legend. Prior to his death, the artist left behind recordings of 30 songs from the mid-1930s. The intensity and authenticity of Johnson's musical expression and his powerful, stark lyrics, combined with the danger and gritty romance of his life, personified the mystique of the rambling bluesman. He lived much of his short life on the road and was killed over a woman. The story circulated, even during his lifetime, that Johnson had stood at a crossroads outside Greenville, Mississippi, one midnight and sold his soul to the devil for the chance to play guitar. The beautiful, tortured sound of such songs as "Hell-hounds on My Trail" and "Come On in My Kitchen" are the mythical products of that Faustian bargain. The results, in terms of his impact on American rock, pop, and rap music, were immeasurable. In the decades since he died, countless musicians have aimed for Johnson's raw intensity, soulfulness, and authenticity as well as his image as a troubadour of mystery.

—Louis Mazzari

by solo guitar or piano, and was the kind of music played at African American picnics and house parties throughout the South, in juke joints and bars, and on street corners and train platforms.

By the end of the 1930s the blues moved along with so many black southerners in the United States—in what historians have come to term "The Great Migration"—to the factories and ghettos of the North. Chicago's South Side became a center for blues clubs and recording studios. The sound became amplified—it was louder and more raucous—and jump blues and boogie-woogie came into vogue. By the late 1940s, the electric guitar had become central to urban black music. Most of the rhythm and blues singers and early rock and rollers played the blues, from Little Richard and Chuck Berry to Elvis Presley and Jerry Lee Lewis. Blues also continued to influence major rock musicians of the 1960s, including the Beatles, the Rolling Stones, and Jimi Hendrix.

The structure of the standard blues is 12 bars of 3 lines, usually played in 4/4 time. The first 4-bar line begins with at least a suggestion of a tonic chord, the second 4 bars moves to the subdominant chord, and then the last 4-bar line moves through the dominant chord to resolve back at the tonic, like so many folk ballads of the late nineteenth century. A line of text goes with each musical line, the second repeating the first, sometimes with a slight variation for effect, before the third line, rhyming with the preceding, resolves the thought of the first and second lines. The form invites short melodic phrases or riffs, an element that has become ubiquitous in contemporary popular music. This structure allows for an accompanying instrument—whether a guitar, harmonica, trumpet, or clarinet—to become a second voice that responds to the song's vocal lines. In a way, the blues is a context for a conversation between a voice and an instrument. The flatted blue note is an African element in the blues, while the form that provides for those blues notes to find resolution at the end of each stanza is a product of the music's Western ballad structure.

The lyrics in blues music are frank and tough-minded, often filled with bravado and desire. The viewpoint is always first-person. Most blues take place in the present tense, and the lyrics are always about the singer's feelings. Most songs are about love and sex, crime and escape, poverty and death, despair, alcohol and gambling, voodoo and fate, topics often beyond the bounds of polite society, black or white.

For decades, the blues was seen by many as devil's music, and the music was associated with the black underworld of pimps and prostitutes, gamblers, drug addicts, and crooks. Blues singers, women and men, were considered low down, and most were products of the poor and dispossessed of the rural and urban South. In later decades, blues lyrics would become emblematic of self-determination and verve in the face of a harsh world.

Radio Entertainment

When wireless telephony, later called radio broadcasting, appeared in 1919–1920, the consensus of most scholars was that it was a harmless fad that would mainly appeal to fans of technology. Few predicted that the fad would soon become a craze, and within a couple of years it would take its place as an essential part of daily life for millions of listeners all over the world.

Among the first countries to broadcast were the United States, Canada, and Argentina, and almost immediately questions were raised about what kinds of programs should be offered. Some early stations were operated by men who believed that radio should be used to educate and uplift the average person. American inventor and engineer Lee DeForest (1873–1961) was typical of this viewpoint. He had tried to broadcast opera on an experimental basis as early as 1910, and when commercial broadcasting began, he never wavered in his belief that popular music was vulgar. Sharing the view that only “good music” was what the public ought to hear, Westinghouse-owned station KYW in Chicago chose an all-opera format when it debuted in late 1921 and featured Chicago’s Grand Opera Company. Even people who were not opera fans were impressed. For the first time they had access to high culture, and they did not have to leave their home or dress up for the occasion.

KYW was not alone in its choice of music. A number of pioneering radio stations debuted by featuring the classics. Argentina’s first station went on the air from Buenos Aires in late August 1920. Its first program was a performance of Richard Wagner’s opera *Parsifal*. In Canada, when the *Toronto Star* newspaper put its radio station on the air in late March 1922, the first broadcast consisted of light classical selections performed by lo-

cal artists such as tenor Victor Edmunds and cellist Boris Hambourg (1885–1954).

Although a majority of early programs were classical, other broadcasters realized that audiences favored popular genres. In cities such as Montreal and Toronto, signals from American stations were easily received, and dance music was winning out over the classics. Canadian stations continued to provide “good music,” but they also began to broadcast local dance orchestras; bandleader Rex Battle and his Mount Royal Concert Orchestra became especially popular with Canadian fans. Also popular in both Canada and the United States were inspirational talks from clergy and women’s shows, where a radio homemaker gave advice about child-raising, cooking, and budgeting. Speeches by politicians also drew favor. American candidates campaigned by radio as early as 1922, and several presidents gave radio talks. In Canada, Toronto radio station CFRB also broadcast election returns from England in 1929.

By the mid-1920s, radio entertainment in the United States no longer represented what certain elites wanted; it was now dominated by the advertisers and corporations that supported the programs. After initially resisting commercials the government had begun to allow them, and advertising agencies often chose the performers for the programs they sponsored. They also named the entertainers after the products: the Cliquot Club Eskimos were a dance orchestra who dressed in costume to represent the soft drink company that paid their salary. American sponsors sometimes supported a classical orchestra, but generally American radio became a mass-appeal medium, oriented toward all types of popular music from country and western to the latest dance hits. America was still racially segregated, but a number of radio stars were black, including such vocalists as the Ink Spots and Ethel Waters. The 1930s in American radio was referred to as the Golden Age of broadcasting because many radio dramas, soap operas, children’s shows, and variety programs became popular. Several radio comedians, notably Jack Benny (1894–1974) and Eddie Cantor (1892–1964), also had millions of fans. And in North America, sporting events were well

➤ EARLY RADIO IN EAST ASIA

In Asia, radio took off much more slowly than in North America or Great Britain. In 1927 there were only three stations in all of China, where the government had long resisted the idea of broadcasting. In Japan, the first station did not go on the air until March 1925, but radio proved so popular that the government soon permitted the industry to expand. The first successful station was JOAK in Tokyo. At a time when women announcers were still rare in broadcasting, JOAK hired a woman, Akiko Midorikawa, as the chief announcer. JOAK and the other stations that followed broadcast news reports, talks, and Japanese classical and folk music. In Hong Kong, the first station, GOW, did not go on the air until 1928, and as late as the mid-1930s only about 5 percent of residents owned a radio. Hong Kong was a British colony, and the government often used radio to reinforce colonial ideas and promote British culture. Much of the programming was in English, and although a Chinese-language service was finally developed in 1934, it was not well funded and was only able to provide Cantonese programs on a limited basis. The British government's control was also reflected in the news broadcasts, which featured stories that favored the British point of view and downplayed any dissent from the Hong Kong Chinese. In the Philippines, a popular station was KRZM in Manila, which hired American broadcasters as advisers. The programming included concerts of patriotic music by the Constabulary Band as well as educational programs and coverage of boxing matches.

—Donna L. Halper

received, especially hockey in Canada and baseball in the United States.

In the United Kingdom where the British Broadcasting System was dominant, the same debate played out about “good music” versus “popular music.” During the first decade of the British Broadcasting Corporation (BBC), some members of its management encouraged only those genres of music that they believed would appeal to upper-class members of British society. Popular music, especially jazz, was identified with the lower class, and while some dance

music and local folk songs were played on stations in Wales and Scotland, the BBC itself tended to focus on symphonies, chamber music, and the most lyrical and melodic modern vocalists. British sporting events were sometimes heard. During the mid-1930s, live broadcasts from the Berlin Olympics amazed the audience, and broadcasts of cricket matches were always welcomed. Also popular were poets and authors who read from their work. During the 1920s and early 1930s, the BBC had a policy that prevented entire plays from being broadcast (there was a belief that doing so would discourage theater attendance); listeners only heard excerpts until the policy was finally changed.

Although under British control, Australia carved out its own path, and by the late 1920s there were 20 stations in operation. One particularly popular kind of program was community singing, allowing listeners to sing along to their favorite songs. Australian stations, like their British counterparts, offered classical and opera programs but, like Canada, also offered dance music, jazz, and local sporting events. In India, in contrast, British control was tighter: All-India Radio avoided politics, focusing on educational and entertainment programs. Due to India's linguistic diversity, programs were offered in seven languages. In Africa, one of the first stations was set up by the British in Johannesburg, South Africa, in 1924. Programs were all in English until 1931, when a few were broadcast in Afrikaans; little effort was made to offer music for non-European tastes.

In other countries, radio entertainment varied. In Mexico an early station was CYL, which called itself *El Universal-La Casa del Radio*, after the Mexico City newspaper that co-owned the station. From its beginning in 1923, CYL provided a hybrid of programs. Catholic mass from Mexico City's most important cathedral was broadcast, as were light classical and opera performances, but equally popular were Mexican folk and dance music and musical comedies from local theaters. By 1928 Mexico had 20 stations. In addition to local music, they offered political talks, church services, and coverage of such popular sporting events as bullfights.

In 1927, American journalist and radio reporter H. V. (Hans von) Kaltenborn (1878–1965)

wrote about his trip to Russia and what he heard on the radio there. All of the stations were government run, and no advertising was permitted. The programming consisted of news from “official sources” along with operas, plays, light classical concerts, and educational talks by experts. He was told that popular music was discouraged. Kaltenborn found the programming more educational than entertaining, but he was told that the average Russian was very pleased with it. Because large numbers of the peasants were illiterate, they relied on radio to teach them about current events, and they were grateful to hear the finest Russian musicians performing.

By the late 1930s as World War II broke out, many stations changed their programming to include a majority of songs that had patriotic themes, and news broadcasts about the war increased. So did censorship. In 1940 Sir Hugh Robertson, conductor of a popular Scottish choir, was temporarily removed from the air because the British government objected to his pacifist views in a time of war. American broadcasters too had to contend with a government censorship agency that made sure broadcasts did not inadvertently help the enemy. The Japanese government turned its radio stations into vehicles for pro-government information, and when Japan took over Hong Kong, the radio stations there reflected the views of the new occupying forces.

Hollywood

The modern motion picture industry was born when Auguste and Louis Lumière held the first public screening in Paris on December 28, 1895. The brothers considered their films to be of only limited interest, but creative businessmen began exploiting the technology almost as soon as it came into existence. Within months, the United States, France, Germany, and Great Britain were developing motion picture industries. Two decades later, films were being shown in urban areas across the world. Many people believed that the future of motion pictures was as an educational tool, but cinema was soon on its way to becoming the world’s most popular form of entertainment.

The United States and France were the pioneers of worldwide marketing. Entrepreneurs from both nations promoted their wares in India, China, Japan, and Latin America before the onset of World War I. During the war as France fought for survival, the United States began dominating the markets. Afterward, the United States held on to its predominance chiefly through greater attention to narrative construction and to the use of grandiose production effects. American films spread the image of an affluent, commercialized culture that was sometimes at odds with existing social norms. Many governments took action to control or minimize the U.S. influence, sometimes in response to cultural imperatives and other times to assist local industries. Still, U.S. films were commercial successes in foreign markets, which allowed glamorized, fictionalized depictions of life in the United States to spread across the world.

The attractive, inexpensive entertainment became immediately popular, although the content was a matter of some concern to local political and social establishments. The most common complaint regarded Hollywood’s use of stereotypes, such as the square-headed Germans,

THE HAYS CODE

In 1930 the Motion Picture Producers and Distributors of America (MPPDA) adopted the Motion Picture Production Code, better known as the Hays Code after MPPDA president Will H. Hays. The Hays Code was essentially a set of self-regulated censorship guidelines used to determine moral acceptability in films. The code was a means of quelling the general outcry over the violent and sexual material that was prevalent in motion pictures, thus both appeasing special interest groups and avoiding direct government oversight. It contained three General Principles that were supplemented by additional, more specific restrictions concerning such things as nudity, obscenity, religion, and offensive stereotypes. The Hays Code remained enforced and intact until 1966.

General Principles of the Hays Code

1. No picture shall be produced that will lower the moral standards of those who see it. Hence the sympathy of the audience should never be thrown to the side of crime, wrongdoing, evil, or sin.
2. Correct standards of life, subject only to the requirements of drama and entertainment, shall be presented.
3. Law, natural or human, shall not be ridiculed, nor shall sympathy be created for its violation.

Will Hays, president of the Motion Picture Producers and Distributors of America from 1922 until 1945, and author of the Hays Code. (Library of Congress)

effeminate Frenchmen, indolent Hispanics, and so forth. The desire to maintain profit margins kept filmmakers in the United States generally responsive to foreign sensibilities. By the 1920s and 1930s, the industry earned approximately 35 percent of its gross income from foreign distribution and could not afford to offend consumers. In 1922, for example, the Mexican government took offense at the portrayal of Mexican villains in Hollywood westerns and placed an embargo on the importation of films from the offending companies. The new U.S. trade association, the Motion Picture Producers and Distributors of America, Inc. (MPPDA), responded quickly. Their representative negotiated an agreement to “do everything possible to prevent the production of any new motion picture films which present the

Mexican character in derogatory or objectionable manner.” Afterward, the Mexican government kept pressure on the U.S. film industry whenever it found offensively stereotyped portrayals of Hispanics. The tension between ethnocentric and economic urges has never been completely resolved. Other groups, realizing the effectiveness of pocketbook protests, have experienced varying degrees of success using tactics similar to those of Mexico.

Whereas some viewers reacted against unfavorable images of themselves, others responded strongly to U.S. films as an escape from the boredoms or frustrations of their daily lives precisely because they did not see the mundane, familiar world portrayed on the screen. The representations and storylines of Hollywood films often

created a desire for a life as free and affluent as the lives seen on the silver screen. Others were disgusted at portrayals of themselves and their compatriots. Some analysts believe that the contrast between reality and the romanticized fiction of the cinema contributed to the dissatisfaction that led to social upheavals and revolutions in places such as Cuba. Certainly, Cuba is an excellent illustration of the complexity of the reactions of local populations to imported movie extravaganzas. Hollywood films were very popular in Cuba and helped shape its identity. Films (and later television) emphasized the country's tropical allure and thus arguably bolstered its tourist industry yet alienated many Cubans. Audiences in the United States and Cuba were gazing at stereotypical representations of each other and envisioning a luxurious freedom missing in their own cultures. Films such as *Week-End in Havana* (1941) portrayed an uncomplicated land of moonlit nights and Latin lovers who were romantic and desirable but also vain, cocky, and irresponsible. Cuba's reality was more sinister and complex.

U.S. magazines, such as the *Saturday Evening Post*, *Time*, and *Variety*, portrayed Havana as "one of the last of the world's sinful cities," and opportunists worked to create a playground to fit the reputation. Some Cubans asserted that they ultimately supported rebels because they found Cuba's relationship with the United States profoundly disturbing and humiliating, complaining that "the Yanquis had turned Havana into the bordello of America" and a criminal headquarters for drugs, gambling, and other rackets as well. Cuba became popular as a vacation site where tourists could escape the moral structures of their everyday life in the United States. The social costs became unacceptably high to many Cubans. The popular images created expectations and demands that were economically attractive for a few in the short term but were ultimately degrading and offensive to the larger population. Cuba's stereotype in U.S. films as an exotic and immoral tropical paradise fed Cuban resentment and dissatisfaction.

Imported entertainment may be alluring, but in the end people want images with some relationship to their own experiences. Although a lucrative market for American films continues,

cultural pride and the lure of profit have led filmmakers and entrepreneurs around the world to begin producing films tailored specifically for local audiences. The cultural webs created by the global diffusion of mass media technology have had a profound impact, if for no other reason than that they inspire people to consider the ways in which their societies and lives differ from others.

Early Non-European Film Industries

While most early experiments with silent film occurred in Europe and the United States, the pioneering inventors—the Lumière brothers and Thomas Edison—demonstrated their moving pictures all over the world. Auguste and Louis Lumière, for example, sent representatives to Mexico City in mid-August 1896. Six weeks later the Lumière Cinématographe was entertaining the public in Sydney, Australia, and by mid-1897 there were few countries the competing companies had not visited.

What happened after the arrival of Lumière and Edison films varied. In many countries, local film production was considered too expensive, so movie theaters continued to import films from Europe and the United States. In Australia, however, the arrival of Lumière and Edison films created an immediate demand for local pictures. The popularity of the October 1896 film *Arrival of the Ferry "Manley" at Brighton* encouraged its producers, Marius Sestier and H. Walter

▶ INDIAN FILM

Motion pictures were an instant success in South Asia. Indian audiences saw their first motion pictures when six short French films, produced by the Lumière Brothers' Cinématographe, debuted in Bombay on July 7, 1896. By 1899 Indians were producing their own works. Feature films arrived in 1917, and cinema became a full-fledged industry by 1920. The addition of sound in 1931 revolutionized production. Not long afterward, filmmakers discovered the magic of the big-production musical, now India's favorite genre. Films produced for Western audiences were often a bit too grim for Indian sensibilities, as audiences there tended to prefer entertaining spectacles with happy endings over the gritty slice-of-life films sometimes favored in Europe and the United States. By the beginning of World War II, Indian film audiences were considered the most devoted on earth, and many people habitually attended favorite movies several times. It was also during this time period that the big-production musical, typically three hours long, became the most popular film type. The raucous, exuberant shows were attended by equally unrestrained audiences who strenuously participated in the entertainment, cheering, hissing, booing, and commenting loudly on the action.

—Carlos Marquez

Barnett, to shoot others. In late 1906 Australia's first feature-length film, *The Story of the Kelly Gang*, was released. It was a then-unheard-of 60 minutes long, and it aroused controversy because some critics felt that it glorified crime. Similar adventure films about "bushrangers" (outlaws and bandits) remained extremely popular until government censorship boards finally banned them around 1912.

In Japan, audiences sought a cinema unique to their country and that utilized familiar customs. One of Japan's first local filmmakers was Tsunekichi Shibata, who began documenting people in Tokyo around 1899. His scenes from Kabuki presentations were first shown in 1904, and in the following year he filmed the Russo-Japanese War. Early silent pictures in Japan required a *benshi*, a narrator who explained the film to the audience and who was considered part of the show. As filmmaking techniques—

such as sophisticated editing and the use of intertitles—developed in other countries, Japanese audiences resisted; they did not want films that minimized the importance of the *benshi*. By 1914 there were nine studios in Japan, mainly centered in Tokyo. Japanese director Norimasa Kaeriyama took the lead in changing earlier conventions, and by the early 1920s some Japanese studios were making films with complex plots, dynamic editing, and actresses (rather than actors, as in Japanese Noh and Kabuki theater) playing the female roles. A few studios resisted the modern style, using a *benshi* as late as 1932, a year after Japan's first talking picture, *The Neighbor's Wife and Mine*. Renowned Japanese director Yasujiro Ozu, who produced masterpieces such as *A Story of Floating Weeds* (1934) and *Late Spring* (1949), began his apprenticeship in the silent era.

While foreign films were popular, local Chinese film industries had emerged in both Hong Kong and Shanghai by 1910. Among the most popular films was the 1913 *Zhuang Zi Tests His Wife*. Hong Kong also exported films to countries such as Vietnam. Because it was a British colony, Hong Kong also had the freedom to make films in Cantonese long after mainland China insisted that films be made only in Mandarin. In Siam (Thailand), American and European films were shown by 1904, but the pioneering film producer was a Japanese businessman named Watanabe Tomoyori. Japanese-made films remained popular in Siam until 1910, when a group of Chinese and Siamese businessmen set up the first local studio. In Taiwan, then a colony of Japan, Japanese films and conventions were dominant throughout the silent era. Japan also had considerable influence in early Korean cinema, although films from Europe and Shanghai were also shown.

In Africa, local film industries were slow to develop. Although films were shown in Senegal as early as 1900 and in Nigeria in 1903, throughout the silent era most Africans saw films primarily from the colonial nations that ruled their particular country. In Egypt, films by the Lumière brothers had been shown in late 1896, and for the next few years a number of European filmmakers visited to shoot scenes of Cairo and Alexandria for travelogues. Later, newsreel

cameramen filmed events that most Western viewers would find unusual, such as Muslim holiday celebrations. But there was little local filmmaking, and the majority of the pictures that Egyptians saw through the 1910s came from France and Italy, with Arabic intertitles added. The man considered the father of Egyptian film, Mohamed Bayoumi, did not make his first movie until the early 1920s. In most other Arab countries, there was also little local filmmaking during the silent era. As they had done in Egypt, European directors also filmed in Tunisia, Syria, and Morocco, with local filmmaking not beginning in these countries until the 1920s.

Several countries in Latin America, most notably Brazil and Argentina, produced local documentaries and dramatizations of history and current events. For example, a 1908 film from Argentina, *El Fusilamiento de Dorrego*, focused on the career of the first governor of Buenos Aires. The 1910 Brazilian film *Paz e Amor (Peace and Love)* relied on satire to critique the country's president. In addition to political and historical subjects, religious films and newsreels were also popular. In Mexico films from the United States dominated, but this became a problem, as many of these films stereotyped Mexicans as criminals. The Mexican government was so irate that in 1922 it threatened to ban U.S. films unless changes were made. During the talking-picture era, film in Latin America expanded. Argentina produced the majority of the Latin American films, exporting many of them to other Spanish-speaking countries. The Mexican film industry also grew and benefited from the contributions of expatriate directors such as Sergei Eisenstein (Russia) and Luis Bunuel (Spain). By 1943 Mexico produced about 70 films a year.

The arrival of talking pictures in the late 1920s and early 1930s was crucial for many countries in forging a national cinema. China found that talking pictures were essential in creating a common culture and a common language. The country's first talkie, *The Songstress Red Peony*, was filmed in Shanghai and released in 1931. China had many widely used dialects, but the film was made in Mandarin. The film featured four songs, sung by the famed opera singer Mei Lenfang, whose voice was dubbed in over that of actress Hu Die. Another important Chi-

nese film was *Street Angel*, a 1937 tragicomedy—with a left-wing political point of view—about the struggles of the urban poor in a corrupt society. In the Philippines, colonized first by Spain and then by the United States, the talkies enabled directors to popularize the use of Tagalog as the country's national language. Successful silent film director José Nepomuceno began making talking pictures in 1933, using only Tagalog. The popularity of *Ang Punyal na Ginto (The Golden Dagger)*, the country's first talkie, led to other equally popular films as the filmmaker's use of Tagalog spread.

Competition with Hollywood was still a part of life for many international filmmakers. Australia's local industry was still struggling in the 1930s and 1940s, and the same was true in Mexico. Although the Mexican industry had grown, the majority of popular films were still made in the United States with dialogue dubbed into Spanish. In Africa only a few films, mostly educational or documentary, were made by and for Africans. During World War II, Japan's film industry thrived. In addition to numerous propaganda films, the nation's industry also produced the first films of critically acclaimed director Akira Kurosawa including *Sanshiro Sugata*, his 1943 film about a judo master.

Film Industry in Europe

When the French inventors Louis and Auguste Lumière began showing short documentary films on their cinématographe in late December 1895, it is doubtful the two brothers expected

YIDDISH FILM

Yiddish cinema was a unique genre of popular film in the early twentieth century that transcended national boundaries. These films targeted Jewish audiences in central and eastern Europe but were also exported to countries with large immigrant Jewish populations, such as the United States. The screenwriters and many of the actors may have been Jewish, but the themes of these films were often universal: familial power struggles, encounters with prejudice, questions of identity, and assimilation. Many of these Yiddish films were made in Poland, Russia, Germany, and Romania. While Yiddish films were also made in the United States, they were of lesser artistic and production quality. With such Warsaw studios as Kinior and Green Film, Poland was at the center of Yiddish film production during the period. Among the best known of the silent movies was the 1912 original version of *Mirele Efros*, starring famed Polish actress Ester Rachel Kaminska, and the 1924 film *Tkies Kaf (The Oath)* from Polish director Zygmunt Turkow.

The arrival of sound proved to be very beneficial for Yiddish films, since a number of the stars came from the theater or had been singers. The 1936 musical *Yidl Mitn Fidl (Yiddle with His Fiddle)* gave audiences a chance to both see and hear well-known entertainer Molly Picon, playing the role of a traveling musician. Many critics believe that the 1937 drama *Der Dibek (The Dybbuk)* was the best Yiddish film ever made. Poland remained at the center of Yiddish film production during the 1930s. *On a Heym (Without a Home)* was the last film produced there in 1939. As persecution of Jews increased during the 1930s, many producers and directors fled to the United States.

—Donna L. Halper

moving pictures to become a national craze. Their first films were brief (about 40–50 seconds) and showed actual events from daily life: workers leaving the Lumière factory, a train arriving at the station, an adorable baby eating, people bathing in the ocean. There was so much demand that the Lumières soon began sending trained camera crews to distant locations to film interesting scenes. By the late 1890s their films

were being shown in other countries, including Germany, Hungary, Russia, and Spain.

France was at the forefront of the silent film industry in those formative years. French motion picture executives Charles and Emile Pathé became very influential, producing and distributing films throughout Europe. Unlike with the early Lumière minidocumentaries, Pathé had studios where events could be staged. In the early 1900s the company was producing comedies and dramas as well as something new: short films that depicted current events. Pathé was able to re-create scenes from the 1905 Russian Revolution, using information gathered from newspapers, and in a further innovation Pathé then introduced the newsreel, a concise look at recent news. Also popular during this time were travelogues, as exemplified by the 1909 Pathé film *Moscow Clad in Snow*.

Because movies were silent, they could be produced in one country and then shown in another. All that was needed for a foreign audience to understand a movie was a translation of the intertitles into the local language. France remained the dominant source of pre-World War I European films, a status that continued into the 1920s. Among the other European nations that had some success in producing silent films was Italy, where new studios like Cines became known for extravagant and lavishly produced spectacles such as the 1913 epic *Quo Vadis*. Italy was among the top three film producers worldwide during that time, competing with the United States and France. Also with a strong local film industry was Sweden, where Victor Sjöström's 1918 film *The Outlaw and His Wife* received international acclaim.

Because movies from France, Italy, and the United States could be imported, German filmmakers did not start producing their own films until 1909, with the local industry not expanding until World War I, when most of the countries from which Germany had imported films refused to do business. A new company, Ufa, was created in Berlin. Ufa's first productions were mainly patriotic, but by the end of the war Ufa and other German studios began producing crime and melodrama films; among the most critically acclaimed was a 1919 thriller directed by Robert

Wiene, *Das Cabinet des Dr. Caligari* (*The Cabinet of Dr. Caligari*) and the 1921 vampire film *Nosferatu*, directed by F. W. Murnau. Fritz Lang's critically acclaimed 1927 film *Metropolis* was also an important German film of this time.

Russia—soon to become the Soviet Union—was home to several international companies, including Pathé Frères. But by 1907 a local industry emerged. Two of the first Russian filmmakers were Alexander Drankov and his rival Alexander Khanzhonkov, both of whom operated studios in Moscow that produced dramatic and documentary films. By 1914 moviegoing had become more popular than attending stage presentations. In August 1919 Vladimir Lenin nationalized the industry, and in 1924 Sovkino was organized. This gave filmmakers much-needed financial support and, initially, freedom to innovate beyond the confines of “bourgeois” narrative forms and to draw from other revolutionary art forms including constructivism with its interest in photo-collage. Among the most admired Soviet directors was Sergei Eisenstein, known for his theory of montage: the rapid juxtaposition of images from different points of view in film editing to create a “collision” on the cognitive level. Eisenstein applied this technique most famously in the 1925 film *Potemkin*, still regarded as a masterpiece. Another important early product of the Soviet film industry that predated Stalinism was Dziga Vertov's innovative and joyous documentary *Man with a Camera* (1927). However, as Stalinism emerged and Soyuzkino was created as the new state film enterprise in 1929, Soviet filmmakers were expected to make films that expressed a vision of the ideal communist state and inspire the masses, a style of filmmaking called socialist realism. In the 1930s Soviet films frequently featured patriotic themes that praised communist heroes, and many filmmakers such as Eisenstein felt stymied as new genres such as socialist song and dance musicals were mounted to counteract Hollywood fare.

In smaller countries like Greece, the showing of American- and French-made silent films, especially comedies, was well received. Early Greek directors like Spiros Dimitrakopoulos often modeled their own silent films after the American and French styles. Also popular were film versions of Greek classical folktales and lit-

erary works, such as the 1927 drama *Prometheus Bound*, directed by Dimitris Gaziadis.

It was not until after World War I that major British-owned studios opened. In 1924 Michael Balcon cofounded Gainsborough Pictures, and during the 1930s he worked for Gaumont-British, where he produced imperialist adventure films such as *King Solomon's Mines* (1937). In 1925 Balcon also hired the young director Alfred Hitchcock, whose reputation as a master of psychological thrillers grew throughout the 1930s.

By the late 1920s when the silent era was ending, about 85 percent of the films sold worldwide were being made in Hollywood. Most European and Mediterranean countries were unable to complete the changeover to talking pictures until the mid-1930s. In some countries, leaders decided that the best way to support the national film industry was through nationalization. Like Lenin in the Soviet Union, Italian leader Benito Mussolini believed that the cinema could be a powerful force in society, and in 1926 he nationalized the Italian cinema. Under fascism, the Italian film industry made many nationalistic and patriotic movies such as *Luciano Serra Pilota*, a 1938 film about a courageous aviator, produced by Mussolini's son Vittorio. But audiences also wanted escapist films, especially comedies like the 1937 film *Il Signor Max*, starring Vittorio De Sica.

A more malevolent takeover occurred in Germany in 1933, when the National Socialists (Nazis) gained control of what had been a highly creative and independent film industry. By the time World War II broke out in Europe in 1939, the German film industry was producing mainly pro-Nazi propaganda films, notably Leni Riefenstahl's 1935 pseudodocumentary *Triumph of the Will*. In addition to films praising Hitler, German directors such as Fritz Hippler created anti-Semitic works, such as the 1940 *The Wandering Jew*.

During the Great Depression, the documentary film evolved in countries such as Britain and the United States as government agencies sponsored films that celebrated the dignity of common people and the value of united social efforts. During the war years most countries used their film industry to disseminate nationalistic

messages and to keep audiences entertained through difficult times.

Migration and Travel

During the first half of the twentieth century, traveling became faster and less expensive than ever before. The invention of the internal combustion engine and its application to the development of automobiles, trucks, airplanes, and ships revolutionized travel and made it available to an increasingly greater number of people, first in the industrialized countries and then across the globe. These inventions coincided with the so-called second wave of the Industrial Revolution, characterized not only by the massive production of consumer goods but also by the shift from coal and steam to oil and electricity as main energy sources. When the economic pressures and the social disruptions of two world wars were added to such new travel technologies, populations became more mobile than ever, and the consequences were enormous.

Nineteenth-century means of transportation were dominated by coal as the main energy source, and the steam engine was used to power locomotives and steamships. Toward the end of the nineteenth century, in addition to electric vehicles, an improved internal combustion engine was developed. The new engine used various kinds of petroleum products, such as kerosene, gasoline, and diesel fuel. The first diesel locomotive started to operate in Switzerland in 1912. Even though the first diesel locomotive was a commercial failure, it had many advantages over the steam locomotive, especially because it was easier to operate and could be managed by just one person. The invention of the internal combustion engine had a similar impact on ocean and river shipping, ending the era of the steamboat that had dominated the nineteenth century. The sinking of the *Titanic*, the largest steamship ever built, in 1912 symbolically marked the end of an era. Diesel engines started to replace steam turbines on ocean liners and battleships in the 1920s, and their advantages were soon obvious, such as decreased susceptibility to fire. The internal combustion engine was the source of power that moved people around in the first half of the twentieth century, even though sailboats, steamboats, and steam locomotives were still used.

The life and travels of Mahatma Gandhi are a good example of how much people traveled. Born to an influential family in the Gujarat Province in northwestern India in 1869, Gandhi sailed to England in 1888 to study law. After completing his studies in London, Gandhi returned to India and started looking for work. Unable to find a suitable job in his native land, he decided to join a law firm in South Africa, where he arrived in 1893. In 1896 Gandhi again traveled to India in order to marry, but he returned to South Africa in 1897. Gandhi stayed in South Africa throughout the so-called Boer Wars while struggling for the civil rights of Indians living there. He finally returned to his native India in 1914

and, at that point his travels were mostly limited to India in the context of the national struggle for independence.

Leon Trotsky is another example of how politics and not just the search for work pushed people across the globe. Trotsky, born in southern Russia in 1879, was arrested for revolutionary activity in 1898 and sent into exile in Siberia. In 1902 he escaped with a false passport and headed to London, where he joined the Russian revolutionary movement in exile. In 1905 after the revolution in Russia, Trotsky returned to his native land, where he was again arrested (1906) and convicted to a second exile in Siberia. He escaped for the second time in 1907 and settled in Vienna, where he worked as a journalist. As World War I started in 1914 Trotsky was forced to leave the country, eventually reaching New York City in 1917. After a brief sojourn he went back to Russia to join the revolution. His role in the Bolshevik Revolution is well known. After the death of Vladimir Lenin, Trotsky lost the power struggle for leadership. Josef Stalin, who succeeded Lenin in 1923, expelled Trotsky from the Soviet Union as a dangerous rival in 1929, whereby Trotsky was offered refuge in Turkey. In 1936 after failing to settle in France and Norway, Trotsky settled in Mexico, which remained his home until he was assassinated by Stalin's agents in 1940.

Such movements of individuals, when regarded from a larger point of view, are indicative of patterns of migration. Migration can refer to short-term movement without the intent to settle and as such is a phenomenon quite common in the animal world and indeed of pastoral peoples who follow their flocks. The term "migration" can also describe movements of people from one region to another to settle permanently, either looking for improved economic or political opportunities or fleeing a calamity in their place of origin. Analysts explaining migration usually refer to the socioeconomic push and pull factors that encourage such movements. Our discussion will consider demographic shifts, international migrations, domestic migrations, and ethnic and forced migrations as well as travel and technology.

An examination of the larger demographic shifts in world population for this period aids in an understanding of overall patterns of mi-

gration, whether voluntary or forced. The overall demographic trends indicate that there was an increase in world population in the first half of the twentieth century, growing from 1.65 billion in 1900 to 2.52 billion in 1950. The main reasons for the increase were technological improvement in food production and better hygienic practices and health care. This population

growth was somewhat hampered by the carnage caused by the two world wars, with World War I claiming 20 million lives and World War II claiming roughly 72 million lives. However, it is important to note that the two wars did not stop the world population growth but instead merely moderated its rate. The largest growth occurred in North America and South America, and the largest decline occurred in Europe. In 1900 Europeans amounted to 24.7 percent of the world pop-

The overall demographic trends indicate that there was an increase in world population in the first half of the twentieth century, growing from 1.65 billion in 1900 to 2.52 billion in 1950.

ulation, whereas in 1950 they only amounted to 21.7 percent. Several factors contributed to this significant drop. First, Europeans migrated to other parts of the world, in particular North America, South America, Asia, and Oceania. Second, the two world wars and associated genocides (most notably the Holocaust) were responsible for millions of dead and wounded in Europe, given the fact that the bulk of the fighting happened on that continent. Third, the population of the rest of the world grew at a much faster rate, leaving Europe proportionately behind. Finally, simply stated, Europeans had fewer children, and the traditional European pattern of marrying later in life and having small families continued.

For the period from 1900 to 1945, migrations are divided into three categories: international migrations, domestic migrations, and forced migrations. International and domestic migrations were largely voluntary, whereas forced migrations were obviously involuntary. Overall, it could be said that the movement was largely from less industrialized agrarian areas to the industrialized hubs of the world, namely western Europe and North America. Thus, for example, the largest international migration of the period was the movement from impoverished agrarian areas of southern and eastern Europe to rapidly industrializing areas of the eastern seaboard of North America and the Great Lakes region. Domestic migrations in China, Italy, Germany, France, Mexico, and the United States also involved the movement of impoverished agrarian workers to industrialized regions. One of the most famous migrant routes in the United States was U.S. Route 61, known as “the Blues Highway,” that led poor blacks from the Mississippi Delta near New Orleans through Memphis all the way to the industrial plants of the Chicago South Side.

This picture of one-directional movement of people, however, is somewhat misleading. The industrialized economy affected the world in many ways, creating several layers of interdependency and allowing for more than one-directional movements of people. For example, many small farmers from either Europe or Asia were forced to migrate and search for land in the areas that were less affected by industrialization and massive food production. Migrants from agrarian southern Italy moved to South America looking not for work but instead for cheap and fertile farmland. Moreover, international diasporic communities offered transnational economic linkages and cultural exchanges between peoples on a global basis to aid such migrations.

The migrations in the first half of the twentieth century were not only limited to voluntary labor migrations but also included forced migrations. Two global wars and numerous local conflicts pushed millions from their homes, in most cases permanently. The two world wars moved most of the world population. In particular, millions of East Europeans were moved from eastern Poland and Belarus during the Soviet invasion in 1939. German policies of forced resettlement in eastern Europe are well known during the period between 1941 and 1944. Long before the war, the Jewish populations of Germany, Hungary, Poland, and the Soviet Union were attempting to leave for British-controlled Palestine in the hopes of finding a safe haven. Millions of East Europeans, an ethnic group considered suitable only for hard manual labor, were

transported to Germany and put into forced-labor camps working for German industrial brand names. Millions of Germans from eastern Prussia and western Poland departed before the advancing Soviet Army and permanently lost their homes. The massive reshuffling of the Soviet population under Stalin displaced so many people from their traditional homelands that the effects are still being felt to this day. Finally, during the many anticolonial struggles, millions of white settlers in former colonies moved back to Europe either willingly or forcibly.

■ Introduction: Urbanization

From 1900 to 1945, the rapid urbanization of much of the industrialized world in Europe, North America, Asia, and Oceania continued the trend that had begun in the prior century. Urbanization was augmented by a vast pattern of international migrations as well as domestic migrations from rural to urban centers, as industry's demands for a larger labor force attracted people in search of employment. Industrialization and modernization shaped the modern city. New York City, London, Berlin, Beijing, Tokyo, Sydney, Mexico City, Moscow, and Buenos Aires, among others, vastly expanded and developed into the major metropolises of their respective nation-states during this period. This growth was aided by the development of urban infrastructure that included new transportation and communications systems enhanced by access to electrical power. Modern architecture allowed for the spatial expansion of cities horizontally and vertically. During the interwar period, the spread of the electrical power network and electrification reshaped factories and homes and brought in new entertainments and consumer products, changing lifestyles for urban residents. Other world regions, particularly in the colonial world, also experienced a boom in the populations of their cities, albeit to a lesser extent, but established a pattern that would vastly accelerate in those regions after 1945.

—*Abraham O. Mendoza*

Trends toward Urbanization in Africa

At the Berlin Conference of 1884–1885, 14 European colonial powers agreed to partition Africa for economic exploitation. After the conquest, the continent was divided and effectively occupied while political systems, regulations, laws, and administrative structures were implanted. Transportation infrastructures were among the key areas of urban development in which colonial authorities invested most of their financial resources in order to secure trade routes. Moreover, the construction of railway systems was never intended to promote regional development. Instead, its main concern was merely to connect the hinterland to the seaports in order to transport goods and products abroad. Likewise, telecommunications were also restricted to urban centers, linking major cities in the colonies with their ruling country in order to transform African cities into European dependencies. The colonial powers established major centers for transportation, marketing, and administration where decisions were made regarding the establishment of capital cities. Places such as Dakar in West French Africa, Ouagadougou in Burkina Faso, and Brazzaville in French Equatorial Africa were established according to the socioeconomic and administrative organization of the territory. In the case of the Congo and Rwanda-Burundi, the Belgians planned and laid out approximately

180 towns with the same purpose. The other colonial powers built new centers displaying distinctive urban patterns and layouts reflecting the cultural influences of their respective colonial rule. As part of establishing the colonial governments' administrative centers, Western institutions such as schools, hospitals, prisons, and churches were created that reinforced their cultural dominance and imposed a particular urban way of life. The construction of transportation and waterfront infrastructures led to the rise of major port cities, such as Dakar in Senegal, Abidjan in Côte d'Ivoire, Takoradni and Jema in Ghana, Lagos and Port Harcourt in Nigeria, Mombasa in Kenya, and Dar es Salaam in Tanzania. It is worth noting that colonial powers discouraged any attempt at developing local indigenous industries in African towns. Furthermore, planning in this context was not effective in dealing with urban problems since underlying economic inequalities were not addressed; instead, regulations were used to reproduce the structural conditions of inequity.

Trends toward Urbanization: Asia and Oceania

During the first half of the twentieth century, urban populations in Asia rapidly increased at rates higher than that of Europe and the Americas. Moreover, Asian urban population growth was responsible for the general rapid increase in the aggregate world urban population of the period. In 1905, Asia had more large cities than did Europe or North America.

Major Asian cities and their growth offer concrete images of urbanization trends in the

region. Kawasaki, Japan, the Asian city with the highest growth rate during the first half of the twentieth century, went from a small village of 4,000 people to a city of 319,000 inhabitants, a seventy-eight-fold increase of total population. The second city was Harbin, China, which grew from 20,000 inhabitants to more than 1 million inhabitants, a transformation that informs one important feature on urbanization trends of the region, which is the recurrent emergence of large cities of populations of more than 1 million inhabitants. By the mid-twentieth century, ten Asian cities had populations that exceeded 1 million people: Harbin, Dalian, Jakarta, Shenyang, Shanghai, Karachi, Saigon, Seoul, Lahore, and Calcutta. It is worth mentioning that by midcentury, Shanghai—with more than 5 million inhabitants—and Calcutta—with

➤ JAKARTA (BATAVIA)

In 1947 Java was one of the most densely populated regions of the world, with an average of over 800 people per square mile and a total of 57 million inhabitants, within which the city of Batavia, later called Jakarta, reached a density of over 3,000 people per square mile. The Culture System, implemented by the Dutch during the nineteenth century, was a major contributor to this population congestion. The system compelled Javanese farmers to give part of their land and labor to commercial large-scale agriculture for export. This led to population growth at a rate of 33 percent per decade in the last phase of its implementation. In 1905 the Dutch government instated a transmigration program, one of the largest state-determined rural colonization policies to prevent overpopulation. Nevertheless, the population of Batavia increased from 116,000 people in 1900 to around 2 million in 1950. This was due to changes in government policy during the first half of the twentieth century with the application of a new approach to overseas governance, known as the Ethical Policy. Batavia became an administrative and economic center, the most modern city in Southeast Asia, and the stage was set for the emergence of twentieth-century nationalist movements for independence.

—Andrea Yuri Flores Urushima

more than 4 million inhabitants—had already reached a metropolitan scale.

Massive growth in major Asian cities reinforced the historical importance of trade, industry, and transportation as premises of urban modernization. The largest Asian cities were important trade-industry centers, strategically located in relation to infrastructural transportation systems. Moreover, with the exception of Karachi, Lahore, and Calcutta, the cities developed under Japanese economic influence and experienced differing levels of colonial rule during this period. Comprehensive analysis is complex not only because of the general lack of comparative statistical references but also due to the fact that this was a period of enormous instability brought about by successive wars and movements for decolonization, paralleled with the emergence and decline of Japan as a regional imperialist state. Even by midcentury, however, Asia was the second least-urbanized continent of the world, behind Africa. This suggests that the region was still largely rural, even though China, Japan, India, and most of the Asiatic triangle from Pakistan to Japan had developed urban centers that existed prior to European colonial expeditions.

Southeast Asian and Oceanian urban traditions were less settled, and the colonial period definitively shaped modern urban development. In Southeast Asia, European and North American colonial rule—which had begun in the seventeenth century—was contested by nationalist movements that developed in major colonial cities that tended to be composed of more educated populations. Australia and New Zealand populations were concentrated in main colonial cities that were less dependent upon neighboring Asiatic countries but more directly connected with Britain and immigration from the British Isles. Similarly, considerable portions of Melanesia and Polynesia had received European migrants and witnessed major transformations due to colonial economic enterprises. Although the urban growth rates during the first half of the twentieth century were not exceptionally high in Southeast Asia or Oceania when compared to East and South Asia, the region had definitively centered around a modern urban

economy and way of living, which resulted in startling postwar urbanization growth.

Generally, urbanization in Asia was stimulated by the world population growth and the establishment of modernization trends at pioneering industrial centers. Modernization—whose fundamental starting point is technological advancement in agriculture, transportation, industrial production, and war industries—spurred new forms of sociopolitical organization. Developed in the context of historical transition from imperial powers to new modern nation-states, these new forms of organization triggered a more integrated global economy, and the industrialization of Asia contributed to them. Industrialization had first transformed cities in western Europe and North America, supported by the supply of materials, labor, and markets from the colonization of foreign territories. Improvements in transportation, which at first supported colonization efforts and international trade, boosted internal migration on an unprecedented scale, evidenced by the subsequent rise of Asian urbanization rates.

Furthermore, once agriculture became more productive and efficient through mechanization and new scientific research, the overpopulation of areas with limited resources pressed internal and transnational migration to the cities and transcontinental migration to other world regions. Widespread migration led to growth in the existing Asian cities and occupation of inhabited areas, especially in Southeast Asia and Oceania. Overpopulated territories, with internal competition for labor opportunities, succumbed to the international demands of new labor markets created by colonial expansion.

Trends toward Urbanization: Europe

Urbanization in Belle Époque Europe reflected the impact of the dual processes of modernization and industrialization. Over the course of the first half of the twentieth century, urbanization would be drastically affected by the contingencies of technological advances, rapid sprawl due to growing populations, and wartime bombing during World War II. From the modernization of urban centers such as the Ringstrasse in Vienna reflecting the impact of liberal ideals in the late nineteenth century to the dull blocks of government housing in the postwar era created by the nascent welfare state, urbanization in Europe during the first half of the twentieth century represents a manifestation of multiple political, social, and economic changes.

The Second Industrial Revolution of the late nineteenth and early twentieth centuries was characterized by advances in the transport, communication, chemical, and energy industries. While urban growth in the first half of the nineteenth century centered on the growth of factories and the unorganized sprawl of working-class housing (resulting in atrocious living conditions adjoining the old city centers outside the old medieval walls), new transportation networks—facilitated by newly built railroad networks and tram systems—allowed for a more expansive city with adjoining suburbs. New building materials, also made available through the products of industrialization, made building *en masse* more affordable and expansive, and massive urban renewal projects in major metropolitan areas such as Paris, Vienna, and Berlin allowed these innovations to restructure decaying urban areas into sprawling modern cities.

The influence of liberalism manifested itself in various public works projects, such as the building of the Ringstrasse in Vienna and of broad new boulevards in Paris. The massive rebuilding of city centers to celebrate the nationalistic and liberal spirit of each nation was represented in beautiful new buildings such as parliament houses, courthouses, and city squares. Art museums, botanical gardens, promenades, cultural centers, and other beautification projects illus-

trated the impact of civic pride and public wealth on the urban landscape. The Houses of Parliament in London are an example of this phenomenon. To a lesser extent, the impact of steel made some of the building of this period vertical, as skyscrapers made limited inroads in the skylines of European cities, although mostly it was put to use in the construction of bridges and railroads. The Eiffel Tower represented this emergent obsession with the potential of modernity and modernization with the possibilities of steel.

Around the turn of the century, socialist legislation in some European cities allowed for the construction of low-income housing for working-class families. The Karl Marx-Hof in Austria is an example of government-subsidized housing using simple designs that provided affordable housing to workers. This type of socialist public housing project would later be used in Weimar Germany in various cities as well as after World War II throughout much of Europe. Socialist parties in Europe advocated for government housing for the lower classes in their platforms.

World War I ignited a period of warfare traversing four years that led to widespread destruction on the western front. However, it also led to a stagnation of government expenditures on infrastructure, as most funds went to war production. European cities became bastions of workers who mobilized on the home front to work in munitions and war-production factories. In the midst of World War I, the home front became pivotal to the pursuit of total war. Trams and trains took soldiers to the various fronts; trucks carried supplies to the rear lines. As such, in this manner the face of war attached itself to the urban landscape.

The interwar period (1919–1939) combined social experimentation with modern architecture. Architects such as Walter Gropius created buildings meant to exemplify the simplicity of modern design with socialist ideals in community housing projects. The social and political liberties of Weimar Germany allowed many of these innovative architectural experiments to thrive. The building of the Paris Métro illustrated the French efforts to create a systemized network of transportation that would integrate

all the metropolitan suburbs with Greater Paris. The building of massive factories in the nascent Soviet Union presented Europe with an example of the possibilities of architecture in the new socialist world, exemplified by beauty, and order for the proletariat masses. The construction of the autobahns in National Socialist Germany as a military measure, but also as a way of constructing highways for the purpose of creating another infrastructural improvement, integrated the Reich economically and politically. Many public works projects undertaken in this period to meet the economic collapse of the Great Depression resulted in numerous infrastructural improvements in urban areas that concentrated on improved roadways, railroad stations, and subway systems. In turn, this changed the dynamic and layout of cities to correspond with the relationship of the suburbs with the city center, which now also included automobiles to a greater extent.

The massive amount of destruction created by the contingencies of warfare during World War II necessitated a massive amount of rebuilding throughout Europe. Britain, France, and Germany sustained immense amounts of damage to metropolitan areas due to aerial bombardment and artillery attacks, not to mention the prevalence of fires in the midst of such attacks. During the war, there was little to no construction in the cities of Europe; most construction took place outside urban areas to conceal worker settlements in an attempt to avoid bombardment. Inside urban areas, there was much in the way of construction of defensive structures, such as bunkers, shelters, and flak towers. These reinforced concrete and steel structures throughout much of Europe are an example of the contingencies of war in urban areas. The widespread destruction of urban areas in the Third Reich necessitated that the government be proactive in ensuring the survival of urban residents in the midst of aerial attacks due to their value as workers for the war industry. The vast destruction suffered by European populations was met by an immense amount of reconstruction, assisted by American auspices in the form of the Marshall Plan in the midst of the Cold War antagonism with the Soviet Union.

Trends toward Urbanization in the Americas

The process of urbanization, the concentration of population in urban centers, is the product of large-scale transformations in the organization of society due to a combination of processes of economic, political, technological, and demographic nature. At the global level, the earliest significant trends toward urbanization were the result of the intensification of international trade and the reinforcement of state power in the eighteenth century that led to the growth of ports and capital cities, respectively. During the nineteenth century, technological innovations and the development of industrial capitalism, which concentrates the labor force in urban centers, greatly accelerated the pace of urbanization. During the twentieth century urbanization trends spread worldwide, not only because of increased industrialization but also due to demographic processes that have pushed populations from rural areas to the cities.

At the turn of the twentieth century, one in eight people lived in urban areas at the global level, and only Great Britain was an urbanized society with more than 50 percent of its population living in urban centers. In the sparsely populated Americas, European immigration played an important role in making the young nations urbanized territories. Argentina and Uruguay became urban nations in the first decade of the twentieth century, while the United States reached this status slightly before 1920. Canada, Cuba, and Chile followed, yet the rest of the Americas was only slightly urbanized during that time, although it had many cities and towns within its vast territory. Unlike the colonization of North America, which began on the northeast coast and ad-

vanced westward, Spanish and Portuguese colonization occurred earlier and was more evenly distributed across the territory. Many cities were located on the Atlantic and Pacific coasts, as colonial trade and mine extraction were the most important economic activities.

Due to the obvious differences between North and South American economic development, urbanization trends developed at different tempos. Whereas 25 percent of the population in the United States lived in urban centers in 1870, Latin America reached that rate of urbanization only in 1925. Its cities began to grow only in the late nineteenth century when European capital was introduced in the region, searching for the raw materials and foodstuffs needed by European nations undergoing industrialization. While North America was industrializing, Latin American nations exported primary commodities—meat and cereals, wool, coffee, cacao, fruit, sugarcane, wood, fertilizers, and minerals—and imported tools, iron, steel, textiles, and other manufactured goods.

Latin America's export-oriented economy favored the growth and development of port cities. Between 1880 and 1920, railroad networks were built to connect the largest ports with inland areas in Argentina, Uruguay, Mexico, Chile, Cuba, Brazil, and Peru. Unlike North America, where the railroad networks gradually advanced westward, structuring the territory and promoting industrial development, Latin American railroads remained monocentric and centralized in the ports. Instead of decentralizing and building up an urban system, they reinforced urban primacy and concentration in the port cities.

The assimilation of these ports into the global trade promoted a flow of European immigration to Latin America, which mainly headed to Argentina, Uruguay, southern Brazil, and Cuba. Most immigrants, however, did not settle in the interior of the country, as was initially intended, but instead remained in the cities, working in petty commerce, the construction sector, incipient industries, or the recently formed state apparatus. Consequently, these countries experienced a swift process of urbanization. On the other hand, urbanization trends did not affect disadvantaged regions with weak transportation systems and large-scale landownership. Although

less extreme than in South America, urbanization trends in North America were also uneven. Striking differences could be seen between the urbanized Northeast of the United States (with 66 percent of its population being urban in 1900) and its rural South (with only 18 percent of its population being urban at that time).

In the nineteenth century, New York City became the unquestionable gateway for European immigrants coming to North America, as the city was a world center for international movements of goods and capital. In 1900 New York City had approximately 3.5 million inhabitants and was by far the largest city in the Americas. Chicago and Philadelphia had approximately 1.7 million and 1.3 million residents, respectively. Buenos Aires, the equivalent of New York in South America, was the fourth-largest city in the Americas, with approximately 867,000 inhabitants in 1900. Rio de Janeiro, the then capital of Brazil, was the fifth largest with approximately 692,000 inhabitants.

The prosperity from their export-oriented economies led Latin American states to modern-

ize at the turn of the twentieth century. A professional class and a state bureaucracy emerged; technical universities were created to train the engineers needed for the feverish pace of the construction sector. The old colonial centers expanded, and the first industries were located on the cities' fringes. Systems for drinking water, sewage, electricity, telephone, and tram-lines were built. Modernization and the new urban facilities also attracted an internal migration flow from the provincial elites.

After World War I, European influence gradually decreased, while that of the United States, in terms of investments and cultural influence, rose. The global economic crisis of the 1930s brought an abrupt end to the export-led economic model in Latin America and a subsequent strengthening of inward-oriented industrialization. Governments imposed high tariffs on imports in order to promote industrialization via import substitution. Urbanization trends intensified because most factories were located in large cities, close to their markets and labor forces. The resulting migration to these urban centers increased their primacy and made regional differences even more pronounced.

New York and Buenos Aires were the most populous cities in the Americas in 1945, but they would not be so for long. Soon after, urbanization trends in Latin America accelerated drastically through a process of demographic transition triggered by improvements in health, food, and hygiene. The subsequent lowering of mortality rates greatly increased natural growth, which in turn resulted in an unprecedented rural-to-urban migration flow.

■ Introduction: International Migrations

The period from 1900 through the 1920s was the apex of the wave of mass global migration that had begun in the 1830s. Per capita numbers reached heights that would not be attained again until the 1990s. European migration to the Americas rose to an average of 1.5 million a year from 1905 to 1914, while Chinese and Indian migration to Southeast Asia reached a peak of 1.25 million migrants a year from 1925 to 1930. The long-distance migration of Chinese, Russians, Koreans, and Japanese to Manchuria and Siberia also increased to nearly 1.4 million migrants a year in the late 1920s. Although much of this migration to northern Asia was not strictly international, it was still very much a part of the broader global pattern of labor migration into cities and resource-producing frontiers.

Migration histories centered on the Atlantic world often date the end of the first wave of mass migration to 1914. Looking at migration from a global perspective, however, makes it clear that the wave lasted into the 1920s. Taken together, the three major flows into the frontiers of the Americas, Southeast Asia, and northern Asia averaged over 3.3 million migrants a year in 1909–1913 and 1925–1929. Even transatlantic migration resumed its momentum after World War I, with up to 1.2 million migrants in 1924, after which it was curtailed by immigration quotas in the United States. The Great Depression marked the real end of this wave, with European migration shrinking to less than 150,000 a year in the 1930s and migration to Southeast Asia dropping by more than half. Migration to northeastern Asia, on the other hand, maintained a

pace of over 1.25 million a year, stimulated by command economies and coerced migration in the Soviet Union and the Japanese empire.

These vast migrations were all linked to the expanding global industrial economy. Factories in Chicago, London, and Tokyo needed laborers as well as the resources produced by migrants in the copper mines of the Congo, the coal mines of North America, the tin mines of Indonesia, and the rubber plantations of Borneo. These migrant workers were among the many global consumers of food produced by other migrants in places such as the newly reclaimed rice paddies of Southeast Asia, the coffee plantations of Indonesia and Brazil, the wheat fields of the American West, and soybean farms of Manchuria. New transportation and communication technologies carried migrants and their products, helped transmit information, and employed many workers.

Barriers against immigration grew hand in hand with the rise of international migration. The mid-nineteenth century was a period of nearly free mobility in which migration restrictions had been abolished in much of the world. In the half century after the 1870s, however, many countries around the world started to restrict migrants according to health, solvency, literacy, political desirability, and race. The 1924 U.S. quota law was the culmination of this trend, a milestone of technocratic management designed to select and manage optimal migration. It established categories of persons, such as merchants, family members, and professionals, who would enjoy free mobility while restricting other migrants to numbers designed to replicate the ethnic composition of the nation at an earlier period. By the 1930s most nations around the world had adopted some form of numerical immigration restrictions. Some nations, especially communist ones, even began to adopt exit restrictions in the 1920s, although these never gained the global legitimacy of immigration controls. Although the racism that motivated the quota laws of the 1920s has now been largely repudiated, the basic techniques of categorizing migrants and selecting them according to some conception of their qualifications and ability to contribute to the national welfare have been maintained and further refined up until the present.

This impulse to manage national populations also generated some of the first huge refugee movements of the modern world. Modern refugee flows have their origins in the population exchanges and expulsions among the Ottoman, Russian, and Austro-Hungarian empires in the nineteenth century, culminating in the expulsion of 1 million Armenians from Turkey in 1915. The emergence of a passport regime after World War I gave this problem a new dimension, as many persons fleeing communist Russia had no passports and were officially “stateless.” The reluctance of many nations to accept the large numbers of Jews fleeing Nazi Germany in the 1930s further brought refugee management into the global limelight, as did the millions of displaced persons in Asia and Europe as a result of World War II. With decolonization and the ethnic and political violence that accompanied the creation of new nation-states in the second half of the twentieth century, refugees have become one of the most visible aspects of international migration.

Migration from Africa to Europe and the United States

While occurring in small numbers, African migration to Europe and the United States began in earnest in the first half of the twentieth century, beginning a trend that would accelerate in the postwar era, particularly to western Europe. The movement of Africans to Europe can be traced back to colonial relationships with European

➤ ALGERIAN MIGRATION TO FRANCE

Algeria was a French colony from 1830 until 1962. Many French, Italian, Spanish, and Maltese workers migrated to Algeria to take part in the growing agricultural industry as well as the rampant land appropriation by the European settlers from the Algerian peasants. Unlike France's other North African colonies, Algeria was integrated into the French state in such a way that Algerians were considered French, to a certain extent. In the early 1900s, Algerian men began to migrate to metropolitan France, entering through the port of Marseilles. Many followed suit, and by 1924 there were more than 100,000 Algerians in the French workforce, primarily in the coal mining, iron, steel, and car manufacturing industries located in Marseilles, Lyon, Saint Etienne, Lille, Strasbourg, and Paris. These men never intended to stay in France on a long-term basis. Rather, they viewed their position as temporary and vital to the financial survival of their families back in Algeria. In the 1920s, French settlers in Algeria, fearing the loss of their colonial labor pool, began spreading propaganda throughout mainland France, stating that Algerians were "criminals" and intrinsically "sexually aggressive." Fueled by these fears as well as a growing anxiety regarding Algerian nationalist movements, the French government carefully controlled Algerian migration into France.

—Jennifer Westmoreland Bouchard

powers in the nineteenth century. In the early to mid-twentieth century, African migration to Europe was encouraged by major European powers as a way to bolster each country's workforce before, during, and between the two world wars. The period 1900–1945 is commonly referred to by migration scholars as the second phase of African migration to Europe. Considered as cheap temporary labor, Africans were viewed as an interim solution to labor shortages and for performing jobs undesirable to locals. As a result of the Great Depression, however, their numbers dropped as jobs became scarce.

Africans were hired on as cheap laborers in the coal mining, iron, steel, and car manufacturing industries in France, the Netherlands, Britain, Belgium, and Germany. It was also common for Africans to be recruited as soldiers during

the world wars. During this period, the majority of immigrants to France and Britain came from each country's former colonies or possessions, due in large measure to the linguistic and political affiliations with their respective metropole. As such, the majority of African immigrants to France came from Senegal, Mali, Morocco, Algeria, and Tunisia, while the bulk of Britain's immigrants came from Gambia, Nigeria, Sierra Leone, and South Africa.

The main migration route for Africans to Europe was through North Africa, passing through either Spain, Italy, the Canary Islands off the coast of the western Sahara, the Spanish enclaves of Ceuta and Melilla, Malta, or the Italian islands of Lampedusa and Sicily. During 1900–1945, typically a combination of land and maritime forms of transportation were used to arrive on Europe's Mediterranean shores.

Voluntary migration from sub-Saharan Africa to the United States began in the 1860s. The first wave of immigrants from Cape Verde included a group of seamen who traveled to Massachusetts to work in the maritime industry. Cape Verdean women followed and were employed in East Coast textile mills and cranberry bogs. Until the beginning of the 1900s, these West Africans were the largest African-born population (except for Egyptians and white South Africans) living in the United States. Nonetheless, their numbers were quite minimal in comparison to other migration waves entering the United States from Europe and Latin America at that time.

In the early 1900s, African students were sent by Christian missions and churches in Africa to black colleges and universities in the United States. These students included Nnamdi Azikiwe (1904–1996) and Kwame Nkrumah (1909–1972), who later became the first presidents of Nigeria and Ghana, respectively. After graduating from Lincoln University, both men pursued graduate degrees at the University of Pennsylvania. With the exception of a few who married and stayed in the United States, the great majority of African students returned to Africa after completing their studies. Many of these individuals contributed greatly to their respective countries' development throughout the rest of the twentieth century.

Africans who settled in the United States and Europe between 1900 and 1945 were all

considered members of the African diaspora. As a result of the diversity of individuals coming from Africa as well as the regional specificities of the European or North African countries to which they migrated, myriad diasporan cultures developed. Each of these diasporan cultures claimed a unique combination of social, religious, and linguistic elements linked to both their former homelands and their host countries.

Migrations from Asia

The years between 1900 and 1945 represent a significant turning point for the global migration of Asians. In 1900 Asian immigrants in many parts of the world faced innumerable challenges, ranging from exclusion laws to violent attacks. With the onset of World War II and the Japanese occupation of East and Southeast Asia, migration trends changed dramatically. On the other hand, the war provided Asian immigrants in Western societies with the chance to flex their political muscle. Consequently, immigrant communities during this period created social, cultural, and

political structures that continue to affect global history today.

During the early years of the twentieth century many predominantly white countries, including Australia, Canada, and the United States, actively blocked Asian immigration. Politicians, labor leaders, and journalists repeatedly portrayed Asians as inassimilable economic threats. Nevertheless, Asians continued to find loopholes that allowed them to move to these countries.

At the same time, other countries encouraged Asian migration. Labor-intensive industries—such as sugarcane cultivation—desperately needed large numbers of unskilled laborers. To meet this demand, they looked to Asia as a source of contract laborers. A typical contract would stipulate that the company would pay for the immigrant's transportation and living expenses plus provide a small wage in exchange for a legally binding labor requirement that lasted a specified length of time, usually three to seven years. Exploitative practices often required laborers to extend the length of their contracts indefinitely.

As Japan's military swept through East and Southeast Asia in the 1930s and 1940s, Asian migration entered a new era. Japanese began settling in many of their newly won colonies. At the same time, non-Japanese Asians living in the West found that they were suddenly considered military allies. This in turn allowed them to expand their political participation in their adopted countries.

To better understand the vicissitudes of Asian migration, it is helpful to delineate the different types of settlers. As mentioned above, contract laborers made up a sizable portion of Asian migrants. For the most part these individuals came from extremely poor agricultural areas, although some were fleeing unbearable debt or other social or legal problems. Predictably, contract laborers were the most powerless of all Asian migrants.

Others had a greater degree of control over their situation. For instance, by the 1930s thousands of Asians had willingly left their home countries to study in prestigious universities in the West or in less prominent colleges in Japan. Upon returning to their home nations these students, including such individuals as Mahatma Gandhi, Deng Xiaoping, and Ho Chi Minh, played a tremendous role in twentieth-century history.

At the turn of the twentieth century, in addition to the gold mines of America and Australia, many Chinese also labored in South Africa. In this photograph, Chinese, African, and European miners work side by side in a South African gold mine. (Library of Congress)

Business immigrants also enjoyed relative freedom of movement. Chinatowns in such cities as San Francisco, Manila, and Bangkok provided moneymaking opportunities to entrepreneurial Chinese. Similar communities existed for other Asian immigrants with adventurous spirits and a healthy dose of business acumen. After succeeding in overseas trade ventures, individuals frequently encouraged their family members and friends to join them in their new environment, creating migration chains.

Asian migrants came from several different countries. By 1900 Guangdong province in southern China had established a long tradition of sending its residents abroad. Although exclusion laws curtailed their travel to North America, Chinese continued to find ways to move to “Old Gold Mountain” (San Francisco) and other cities in the United States and Canada. Others chose to go to the Caribbean or to Latin America instead. Still others chose Europe as their migration destination. During World War I, young Chinese men dug trenches along the western front. After the war, many of them stayed to study in Paris and other French cities. Although not as numerous, some Chinese immigrants relocated to the islands off the southeast coast of Africa, creating sizable Chinatowns in places such as Mauritius.

Yet the most popular destination for Chinese migrants was Southeast Asia. The British, Dutch, and French colonies in Southeast Asia drew hundreds of thousands of Chinese settlers.

South Asian Indians also migrated in large numbers between 1900 and 1945. Originating primarily from the Punjab area in India’s northwest, many of these travelers initially chose to go to Canada. Because both countries had colonial connections with Britain, Indians could move to Canada with few legal restrictions. Fearing a so-called turban tide, Canadian officials created new requirements designed to limit Indian immigration. Consequently, Indians increasingly chose to migrate to the United States and Europe. Others decided to travel to non-Western societies. Sikh laborers, for instance, worked in African colonies helping to build railways and roads. Indians also traveled in large numbers to Guyana, Trinidad, Fiji, and British Malaya.

Although Japan was more economically developed than either China or India, it nevertheless provided many of the immigrants of the early twentieth century. Many Japanese traveled to work as farm laborers in California and other western states. Some Japanese immigrants were contract laborers on Hawaiian plantations or in Peruvian mines. After colonial territories were secured in Taiwan, Korea, and Southeast Asia, millions of Japanese settled in these areas. Ironically, concurrent with Japanese migration to these colonies the Japanese military forcefully relocated thousands of Koreans to Japan to work in dangerous war-related industries.

The Philippines served as a fourth source of Asian immigration from 1900 to 1945. The imperialist ties between the Philippines and America opened the door for Filipinos to settle in California, Washington, Illinois, and other parts of the United States. After arriving in their new homes, these individuals soon realized that they were subjected to various discriminatory laws ranging from antiscegenation legislation to education-exclusion regulations. Besides the U.S. mainland, Filipinos also worked on plantations in the U.S. territory of Hawaii.

Koreans, Vietnamese, Indonesians, and other Asians also added to this large migration of humans. Asian migrants from all of these regions reacted and contributed to the tremendous tech-

nological, political, cultural, and military changes of the early twentieth century.

Migration from Europe

The turn of the twentieth century witnessed a series of mass migrations from Europe to various parts of the world, including North America, Latin America, and Africa. Southern Europe experienced mass movements more than any other region after the 1920s, whereas most prior migrations came from the north European countries such as Germany, Ireland, and Poland. Several factors caused these mass migrations, including the development of nation-states in Europe and the Great Depression, which adversely affected living conditions for the middle class. While poverty and increased population density pushed middle-class Europeans to migrate, various host countries also adopted policies to encourage immigration.

Many citizens of southern Europe, particularly from Italy, engaged in farming at the turn of the century. Conditions in Europe began to decrease the ability of families to earn a living in agriculture amid a growing industrial society. At the same time, national politics favored industrialization, often at the expense of the needs of small farmers. Whereas most immigrants to North America settled in urban centers such as New York City, those who maintained a rural lifestyle predominately immigrated to South America.

Prior to World War I, U.S. policy and culture favored immigrants from northern Germany and Poland, in part due to the societal preference for

Anglo-Saxon and Nordic peoples, as well as Protestant immigrants. In addition, the United States already had a growing German population in regions like Wisconsin and Pennsylvania that was receptive to German language and culture. Following the war, however, the German language experienced a decline of popularity in U.S. society, and the number of German newspapers published in the United States dropped significantly.

Businesses in both North America and South America still viewed immigrants as a major source of labor, and southern Europeans began to dominate the immigrant population. Although large numbers of the immigrants during this time period came from Italy, a significant number of them also arrived from eastern Europe and Russia, of which many were Jews.

In the nineteenth century male immigrants outnumbered female immigrants, but by the turn of the twentieth century the gender bias began to level out. This was partly due to the large number of Italian immigrants who tended to relocate with entire families. On some occasions immigrants who became wealthy sponsored the migration of other family members in what was termed chain migration. Large numbers of Jews from central Europe also migrated to North America during this period, with large numbers residing in New York City. As with most immigrants of all ethnic backgrounds, they settled in fairly homogenous urban neighborhoods and worked in particular industries. Many Jewish immigrants worked in the bustling New York City garment industry, whereas Chinese immigrants in California worked on railroads. In total, the majority of European immigrants to North America settled on the east coast. European immigrants to the United States peaked in the first decade of the 1900s and continued to decline until the post-World War II era, at which time immigrants from other areas such as South America and Asia became dominant.

The predominance of Catholicism in many southern and eastern European communities created friction for those immigrants when they migrated to the United States. Whereas Catholicism and Judaism led to differing levels of discrimination in the United States, the predominance of Catholicism in South America led countries such as

➤ IMMIGRANT DISEASE INSPECTION

Doctor examines immigrants arriving from Europe for skin diseases at Ellis Island, 1902. (Library of Congress)

In addition to their observations while in transit, as immigrants arrived in the United States at Ellis Island (New York), they were observed and examined by public health officials for a variety of symptoms and diseases, including cholera, tuberculosis, epilepsy, influenza, and trachoma. If an immigrant appeared sick, they would be sent to the Ellis Island hospital for further observation and/or care. If, on the other hand, an immigrant was diagnosed with an incurable disease, they would be excluded from processing and returned to their foreign port of departure.

—H. Micheal Tarver

Brazil and Argentina to actively recruit from regions such as southern Italy. However, these recruiting methods were informed by various stereotypes of southern Italians such as possessing predisposed inclinations toward large families.

Of all South American countries, Brazil and Argentina attracted the largest numbers of European immigrants during the 1930s. This was partly due to government policies in conjunction with plantation companies that actively recruited southern Italian immigrants and paid for their initial passage. These plans specifically targeted the migration of entire families since companies thought that this would prevent internal

migration of workers and thus add stability to the labor force. However, neither country was prepared for the large influx of immigrants that occurred. Most immigrants faced difficult living conditions and often spent long periods in holding locations at ports awaiting an assignment to a plantation. Once the immigrants were on the plantations, business owners used a system similar to debt servitude to keep them on farms.

By the late 1930s and early 1940s many Italian immigrants began to move away from plantation housing. Some immigrants began settling their own communities beyond plantation borders or migrated to the cities looking for wage labor. Along with Italian immigrants, Jews also made up a large number of European migrants to South America. During this period many Jewish immigrants arrived from Russia. Although Italians migrated largely due to declining economic conditions, many Jews, who faced increasing discrimination, hoped to escape racism in Europe by starting farms in South America. Both of these migrant groups faced different levels of discrimination in both South America and North America. The economic and social freedoms that most migrants sought were only partially realized, as the Great Depression and racism continued to affect economic and social mobility.

Africa, while on a smaller scale, was also a recipient of European migrations during this period. Most European countries that possessed colonial holdings in Africa restricted migration to colonial officials and missionaries, who often stayed for a limited time. Prior to World War I, a limited number of immigrants from Germany settled in German African colonies such as Cameroon. However, migration from Europe to Africa was not significant during this period for several reasons. Considering the world wars, movement to Africa was often relegated to military personnel and officials who did not plan prolonged stays. When Europeans did migrate to Africa, they tended to congregate to coastal areas such as in Nigeria or the arid plains in Kenya. Racism dominated politics, and white settlers often controlled the most fertile regions and left the poorer lands to Africans. In Kenya, this developed into long-lasting strife between the two groups and led to the Mau Mau

Rebellion (1952–1960), which the British brutally suppressed.

Migration to Europe

At the beginning of the twentieth century, migration involving Europeans was characterized primarily by the flow of people from Europe to the outside world and the few who would return from their short sojourns abroad. There was also considerable migration from Eastern to western Europe due to employment opportunities in industrial regions such as the Rhineland in Germany. The dislocations created by World War I caused a massive refugee problem that resulted in a further movement of Central Europeans toward the northwestern part of the continent. The economic and political collapse brought about by the Great Depression ended most immigration outside of Europe in addition to precipitating xenophobic legislation that greatly diminished intra-European migration. World War II created a massive flow of migrations of coerced labor, ethnic expellees, and war refugees, resulting in a tremendous exchange of populations immediately after the global conflagration.

European migration to the United States, Latin America, and the British empire characterized much of the immigration history of early twentieth-century Europe. Thousands of Italians, Russians, Britons, and Poles proceeded to immigrate to the United States, while residents of the British Isles had access to the white dominions of the British empire such as Australia, New Zealand, and Canada. Thousands of Italians and Germans went abroad to Argentina and Uruguay

alongside people of various nationalities who migrated to Brazil, which was always eager to attract European migrants. There were instances in which some immigrants only went abroad to work for a short period and eventually returned home to settle with the economic gains made in their sojourns overseas. Some workers followed merely seasonal work from Europe to the Americas, not really setting down any roots. European anti-Semitism in the late nineteenth century and early twentieth century triggered the emergence of political Zionism, which helped encourage the vast migration of Jews to Palestine. In essence, the great bulk of migration during the first half of the twentieth century was characterized by net migration out of Europe.

Internal migration within Europe was characterized by the movement from rural to urban areas within nation-states as well as international movement from east to west and south to north. France and Germany, which were both rapidly industrializing, attracted Italian and Polish immigrants eager to fill the labor pools of industry. French industrial regions in Alsace-Lorraine gathered considerable numbers of immigrants as industrial workers, and Germany's industrial regions in the Ruhr and the Rhineland had considerable settlements of Polish and Italian workers. Immigration patterns within Europe reflected cultural affinities among nation-states owing to historical ties, alliances, and geographic proximities. Labor needs on the part of industrializing European nations allowed them to actively seek workers abroad.

The outbreak of World War I ended both external and internal migration within Europe. From 1914 to 1918 there was negligible movement among Europeans, as they were needed at home to work for the war effort of their respective nation-states. The end of the war and the collapse of the German, Austro-Hungarian, Ottoman, and Russian empires as well as the resulting creation of their successor states (i.e., Czechoslovakia, Yugoslavia, Poland, Austria, and Hungary), created a situation characterized by massive population exchanges, millions of refugees, and stateless people. The League of Nations, newly created by the Treaty of Versailles in 1919, attempted to offset the catastrophic problems of large numbers of stateless people

and changing borders by persuading these new countries to protect the rights of national minorities. In the interwar period (1919–1939), new nation-states such as Czechoslovakia and Poland had to accommodate the rights of Germans detached from the prewar German Empire. An influx of Jews from eastern Europe into Germany also created much resentment among right-wing nationalist groups such as the National Socialists.

The economic and political collapse caused by the Great Depression in the 1930s triggered massive changes in European migration patterns. Autarkic economic policies and restrictive immigration legislation hampered movement both outside and inside Europe. Fascist and National Socialist ideologues accused immigrants of Slavic or Jewish ancestry of contaminating the nation-state with their presence. Overall, the restrictive environment and instability during this period hampered migration considerably, although coercive legislation led to considerable Jewish emigration from Germany to Palestine or adjacent countries, at least by those who could afford it.

The outbreak of World War II ended European emigration from the continent to the outside world for the duration but spurred internal movement due to National Socialist policies regarding slave labor, the relocation of ethnic Germans, and the Final Solution to the Jewish question. Slave labor was implemented to augment the massive war industries necessary to ensure German military capabilities. Millions of French, Russian, and Polish citizens as well as many others were drafted for work inside Germany to free up millions of German men for combat. Millions of ethnic Germans were relocated from eastern Europe, primarily from territories belonging to the Soviet Union under treaty (Nazi-Soviet Pact, 1939), and were settled into areas recently seized from Poland, while the Poles were forcibly removed into the General Government (Eastern Poland). European Jews throughout Europe were forcibly seized, dispossessed, and shipped to ghettos in Poland. Given the stalemate of the war against the Soviet Union that had begun in 1941, the German policy toward Jews shifted from resettlement to extermination as German authorities were unable to resettle them in the provinces of the East as previously expected. Concentration camps in the

East were fitted with adjacent death camps, especially equipped to kill Jews en masse by gassing and disposing of their corpses quickly.

Following 1945, the massive dislocations of millions during the war in addition to a redrawing of borders and the beginnings of the antagonisms of the Cold War created a chaotic situation. Millions of displaced persons, among them the Jewish survivors of the Holocaust, had no country to which they could return. Drove of Germans expelled from the territories now occupied by the Red Army flooded westward into what would become West and East Germany. Former slave laborers returned to their countries after years abroad in deprivation and bondage. Millions of civilians whose livelihoods had been destroyed by the war sought to rebuild their lives abroad by moving to countries such as the United States, Australia, and Canada. In order to fill the depleted labor pools and to help rebuild their domestic economies, Britain, France, and Germany sought overseas guest workers from former colonial dominions and economically peripheral regions such as India, Algeria, and Turkey.

Migration to Latin America

Mass migration to Latin America in the postcolonial period begins with the mid-1800s' boom in steamship transportation that brought the greatest numbers of southern and eastern European settlers into the large cities of the temperate southern regions of the Americas, especially Buenos Aires, Montevideo, and São Paulo. During the period 1851–1924, some 46 percent of all immigration to Latin America was destined for

Argentina, 33 percent for Brazil, and 4 percent for Uruguay, this last case being especially remarkable given the republic's relatively small area and population base. The 1880s marked a turning point for immigration in most South American countries, beginning a major wave lasting until the 1930s with relatively minor declines during conflicts and times of economic weakness. The history of migration to Latin America during 1900–1945 entails several key flows of people, but the primary influx comprised these urban-bound Italians, Spaniards, Portuguese, German, and French as well as various Slavic nationalities from within the Austro-Hungarian and Russian empires and eastern Mediterranean groups from what was then the Ottoman empire. It is estimated that during the period 1854–1924 among the 11 million European immigrants to Latin America, 38 percent were Italian, 28 percent were Spanish, and 11 percent were Portuguese, while French, German, and Russian immigrants represented roughly 3 percent each, patterns that did not drastically change until immigration as a whole declined significantly in the late 1930s.

Jews were a part of these European movements, most of them Ashkenazi but also including numerous Sephardic arrivals, especially from Ottoman-influenced areas. Beyond European immigrants there were important Asian flows during this period, with the Japanese being the most sizable group and most significant in Brazil. Overall these varied inflows represented largely economic migrations, although persecution played a greater role in driving relocation for some, particularly those from crumbling empires.

Latin American countries became independent from Spain and Portugal mostly in the first half of the 1800s, with the notable exception of Cuba. There were few major inflows until the Southern Cone (Argentina, Uruguay, Chile) began to industrialize vigorously after 1880. Immigration increased drastically, fueling the industrial workforce, the commercial middle class, and urban populations generally. The numbers of European immigrants coming to the Americas in this turn-of-the-century period were similar to those in the settler societies of British dominions. After the United States (32.6 million European immigrants), Argentina received the most

(6.5 million) followed by Canada (5 million), Brazil (4.4 million), and Australia (3.4 million); in descending order, Cuba (1.4 million), South Africa (731,000), Uruguay (713,000), New Zealand (588,000), Mexico (270,000), and Chile (90,000) rounded out the top immigrant destinations for Europeans in the period 1820–1932.

Italians were migrating to all of the above destinations but especially North America, Australia, and the Southern Cone. Emigrants from across Spain went primarily to Latin America but especially to Argentina and Cuba. Together, Italian and Spanish arrivals made up the bulk of immigrants in the Southern Cone, where their experiences differed from immigrants of the same period in North America for three major interconnected reasons: first, immigrants in South American were coming to societies with somewhat lower levels of capitalist development, which made their existing skills superior to many residents; second, immigrants held relatively high social status among the receiving populations; third, the size of receiving societies was smaller than in the United States, facilitating assimilation. In Buenos Aires, for example, residential clusters representing ethnically specific neighborhoods did exist, but generally there was much dispersion of Italian, Spanish, and French immigrants among native Argentines in the city. In the Brazilian cities of São Paulo, Porto Alegre, and Rio de Janeiro, there was important Italian immigration but also an important flow of Portuguese nationals.

Several other important groups entered at this time. In the same cities mentioned above there was a notable German presence (both Jewish and non-Jewish), which helped cultivate a middle class of urban merchants. In Argentina and Chile a numerically small but economically significant influx of Britons managed large infrastructural utilities, commercial ventures, and export operations through ties with agricultural landowners. Arab immigrants were also key in the sector of urban commerce. Often called *turcos*, even in the present, they came in their largest numbers between 1900 and 1930 from what is now Syria, Lebanon, and Armenia, which were then within Turkish-controlled Ottoman territory. Records show that in the period 1896–1924 some 132,500 Middle Easterners immigrated to

➤ ASIAN IMMIGRATION TO LATIN AMERICA

Traditional thinking about migration to Latin America around the turn of the twentieth century focuses on flows originating in Europe. Indeed, the largest numbers of new arrivals at that time did hail from the Mediterranean region, with Italians, Spaniards, and Portuguese constituting 77 percent of all immigration to Latin America during 1854–1924. However, there were also important influxes of Japanese and Chinese, followed in later periods especially by Koreans, to several Latin American countries. In Brazil from 1900 to 1949, while those same Mediterranean groups combined to form 86 percent of all immigrants, the Japanese made up 5.7 percent, ahead of both Germans (4.5 percent) and Middle Easterners (3.5 percent).

Chinese merchants came to Mexico mostly before the revolution in 1910. Intermarriage with native-born Mexicans was frequent but commonly the focus of derision in popular culture. Xenophobic views of Asians were an easy fit with the strictly binary vision of postrevolutionary Mexican nationalism that upheld indigenous and Spanish influences as the basis of contemporary Mexico. This worked to the ideological exclusion of not only Chinese but also Japanese and numerous Arabs. Nonetheless, there was general upward economic mobility among these groups.

Although there were a few thousand Japanese populations settling in Peru (33,000), Mexico (14,500), and Argentina (5,400) at the beginning of the twentieth century, the largest flow from Japan by far was to Brazil. Some 188,000 Japanese citizens arrived in Brazil between 1899 and 1941, the period of greatest influx. This made Brazil the second-largest destination in the world for Japanese immigrants from the late 1800s to the

mid-1900s, second only to Hawaii (which was not yet an American state) with 231,180 and ahead of the mainland United States, where 197,253 Japanese arrived. Although many had intended to come temporarily, improve their economic fortunes, and return to Japan within a few years, from the Great Depression onward this was no longer feasible. Although there was not the same internment impulse in Brazil as in the United States, Canada and Peru—as well as forced relocation policies in Mexico—during World War II, there were significant social changes for Brazilian Japanese communities at that time. Nationalist policies in Brazil after the 1930s restricted facile short-term migration that would accumulate and export wealth. The same spirit also required greater adoption of the Portuguese language and Brazilian institutions among resident Japanese. Early concentrations of Japanese settlement in Brazil were in southern agricultural areas. However, through the 1950s there was extensive migration to the metropolis of São Paulo and a shift to urban employment. The São Paulo neighborhood of Liberdade (“Freedom”) represents the symbolic heart of Japanese Brazil, yet there is extensive residential integration of Japanese-descent Brazilians across the urban region within the middle and upper economic echelons.

Today Brazil is home to the greatest number (1.5 million) of people of Japanese descent outside Japan, far surpassing the United States or Canada. There is also a significant flow of Brazilians to Japan in search of work as well as permanent relocation. More than 200,000 Brazilians live in Japan today, many of Japanese descent.

—Ryan Centner

Argentina, while 7,826 entered Cuba during the same period. From 1900 to 1949 there were 114,848 Middle Eastern arrivals in Brazil, representing 3.5 percent of all immigration and placing this group behind Spanish (42 percent), Portuguese (29 percent), Italian (15 percent), Japanese (5.7 percent), and German (4.5 percent) entrants to Brazil in this period. Aside from the general “Turk” category, which could have indicated anyone from anywhere in the Ottoman empire, the national groups of Syrian and Lebanese

were the largest Middle Eastern categories. In Brazil alone between 1884 and 1939, Syrians made up 72 percent of arrivals from the region; Lebanese constituted 18 percent. The great majority of them were not Muslims but instead were Catholics (65 percent of all Ottomans in Brazil) and Greek Orthodox (20 percent in Brazil) who fled persecution, eventually flourishing in Latin America as urban entrepreneurs. Although there are important Syrian-Lebanese and other Ottoman-origin populations in many countries of

Latin America from Mexico to Colombia to Venezuela, the largest destinations at the time were Argentina and Brazil, which are also home to the most prominent communities of descendants today.

Nonurban immigration was also formative. Most noteworthy are the immigration of Irish farmers into Argentina and Russian Jewish farmers in Brazil, the influx of Japanese into rural Brazil and Peru, and the expansion of previously existing but remote German colonies in southern Brazil. British newcomers, especially in Argentina, took up ranching, which linked with compatriot exporters in Buenos Aires to provide an enormous supply of beef to Britain.

Immigration also occurred to other parts of Latin America. However, perhaps only Cuba was as extensively shaped by immigration as Argentina, Brazil, Uruguay, and Chile. The island nation is exceptional in that it is the only major long-term migration destination for Europeans in history with a tropical location. Colonial rule until 1898 facilitated a continuous flow of Spaniards unlike in the rest of Latin America, but after 1900 immigrants from the Canary Islands became especially important in both commerce and agriculture. Elsewhere, especially in the Caribbean and Central America but also in landlocked Bolivia and Paraguay, immigration was quite insignificant during this period. Mexico, Colombia, Venezuela, and Peru all received some amount of immigration from the disintegrating Austro-Hungarian and Ottoman empires at this time, with these arrivals mostly taking up work as urban merchants as in their southern counterparts, but the numbers were much smaller.

Migration to North America

In the first half of the twentieth century, immigration into North America was sustained by high numbers of European immigrants mainly from Southern and eastern Europe and to a lesser degree from the British Isles and northern Europe, which had traditionally been the countries of origin for most immigrants to North America in the latter half of the nineteenth century. Both the United States and Canada received millions of immigrants between 1900 and 1914, but this trend ended with the outbreak of World War I. Furthermore, postwar anxieties over labor shortages, political radicalism, and widespread racism made both the U.S. and Canadian governments eager to curtail immigration from Asia and Southern and eastern Europe. Immigration from Latin America, mainly from Mexico, and the internal Great Migration of southern blacks to northern cities, sustained U.S. labor needs after cutting off the spigot from Europe. Canada sought to attract immigrants from the British Isles, but labor necessities made it reluctantly accept other Europeans from less desirable regions. Toward the end of World War II,

➤ IMMIGRANT FAMILIES ANGLICIZE NAMES

In the early 1900s large numbers of southern Europeans continued to immigrate to the United States. Families such as the Salvatore and Maria Di Nuovo family in this photograph moved from Vicari, Sicily, to the United States in search of a better life. Many of the newly arriving immigrants also changed their names to more Anglicized versions; in this case Di Nuovo became Denova.

—H. Micheal Tarver

(Photo courtesy of H. Micheal Tarver)

both the United States and Canada made greater concessions to immigration from their Allies and from occupied Europe, allowing great numbers of displaced persons (DPs) to enter North America.

At the turn of the twentieth century, America was seen as a paradise by potential immigrants wishing to leave their socially and economically circumscribed situations in Europe and Asia. Both the United States and Canada had a tremendous need for labor as their economies industrialized and expanded. However, as the economic situation in northern Europe improved, particularly in Britain and Germany, the numbers of immigrants from those regions were drastically reduced. Protestant Britons and Germans were seen by both Canadians and Americans as the most desirable types of immigrant, as they were perceived as kith and kin and as easily assailable to national values. However, labor demands and economic dislocation in southern and eastern Europe al-

lowed for increased immigration from those areas. Jews, Slavs, and Italians, with their religions and cultural folkways, were not seen as potential Americans or Canadians but were accepted nonetheless, however reluctantly, to fill labor needs. In contrast, on the West Coast immigration from China and India was severely curtailed in both countries due to racist attitudes and growing xenophobia of the so-called Yellow Peril emanating from the East, with both the U.S. and Canadian governments responding to popular demands.

The outbreak of World War I in 1914 ended immigration from Europe altogether, given the situation on the high seas and the inability of people to leave for safer shores. Considering the high number of men in uniform, U.S. labor needs desperately required the use of other sources of labor. Filipino and Mexican farm laborers filled the gap in agriculture created by the war and by the growing number of black workers who had begun to move to the northern industrial centers in order to fill positions formerly held by white servicemen. These positions were potentially filled by eastern and southern Europeans. Continuing a trend begun early in the century, Puerto Ricans immigrated to New York City in large numbers seeking employment opportunities given their status as a U.S. colony. Following the end of the war and in light of the political situation abroad, namely the Russian Revolution and other upheavals in Europe, Americans, wary of anarchists and communists, demanded further restrictions on European immigration. The postwar Red Scare and the Sacco-Vanzetti Trial in the United States fueled domestic anti-immigrant attitudes further, spurring the growth of nativist organizations such as the Ku Klux Klan. Furthermore, as U.S. servicemen returned, employment opportunities granted to Filipino, Mexican, and black workers ceased. Widespread xenophobia and racism led to the Immigration Act of 1924, which severely restricted immigration from southern and eastern Europe. However, it had the unintended consequence of creating a greater need for Mexican and black labor to fill the gap created by the removal of the major source of U.S. immigration up to that point. Canada also faced labor shortages due to the fact that it lost immigrants who moved to the United States after spending a short time in

Canada. Wishing to offset this dire situation, Canada actively recruited for potential immigrants in interwar Britain, ravaged by economic and social instability. The numbers did not prove adequate to meet Canada's labor demands, and government officials reluctantly accepted greater immigration from southern and eastern Europe. However, the Great Depression in both the United States and Canada forced immigration to slow down throughout the 1930s under the economic constraints imposed by declining unemployment.

The international situation abroad, particularly given the rise of fascism in interwar Europe, also spurred restrictions on immigration. German Jews seeking asylum abroad were effectively barred from both the United States and Canada. However, small numbers of exiles from Europe were able to find safe haven as the situation in Europe worsened. As the grip of National Socialism in Europe tightened, the United States and Canada further restricted immigration amid the continuing economic slump. Also, Mexican immigration was halted completely, and large numbers of Mexican laborers, both foreign and native to the United States, were deported to Mexico in order to secure jobs for Americans. However, Canada continued to work in attracting British nationals to emigrate, as Britain too was eager to populate the self-governing dominions in its hope of creating imperial solidarity. The outbreak of World War II in 1939 ended all immigration into North America.

As growing exclusion had been the order of the day preceding the war, the closing years of the war saw an ebbing in racist and exclusionary immigration restrictions in both the United States and Canada. The need for Mexican farm labor was again recognized, and arrangements were made with the Mexican government for these *braceros*. Exclusionary legislation against Chinese immigrants was lifted in both the United States and Canada, given China's status as an ally against the Japanese. Upon the cessation of hostilities in 1945, both the United States and Canada took in great numbers of DPs from Europe to fill labor needs. Also, the Holocaust convinced their respective governments to take large numbers of Jewish survivors, especially in light of their previous reluctance to accept Jews during the interwar period. War brides, married

by U.S. and Canadian GIs stationed abroad, also entered North America at the end of the war.

Migration to Oceania

Three distinctive features demonstrate the complex migratory movements in the region known as Oceania. Both a geographical and geopolitical region in the South Pacific Ocean, Oceania encompasses Australia and New Zealand and their dependencies, as well as the subregions of Melanesia (including Fiji, New Caledonia, Papua New Guinea, Solomon Islands, and Vanuatu), Micronesia (including Guam, Kiribati, Marshall Islands, Nauru, and Palau) and Polynesia (including Samoa, Cook Islands, French Polynesia, Niue, and Tonga). Oceania, like other parts of the world in the late nineteenth century, was drawn into the global flows of trade, investment, and migration that were shaped by European imperial expansion and the transnational integration of economic and political activity. These processes transformed the region's demographics, politics, and economies.

The complex migration into Oceania can be characterized by the following three features. First, British migration to Australia and New Zealand since the late eighteenth century was a direct product of British convict transportation and empire-building in the Pacific Ocean, and both Australia and New Zealand emerged as settler colonies in the expanding British empire. Second, the Melanesian, Micronesian, and Polynesian islands fell under the sway of various Western powers, and intransigent migration in

THE WHITE AUSTRALIA POLICY

The White Australia Policy emerged during the colonial era out of a long tradition of racially motivated immigration practices that heavily favored European, primarily British, immigrants. There was enormous political and popular opposition to non-European immigrants, namely Chinese and Pacific Islanders, who arrived in Australia during the gold rushes or as cheap labor for rural plantations. By the time of the federation of Australia (1901), a national identity was already closely tied to the notion of a white homogenous society. To maintain such a society, the government, nearly unanimously, passed the Immigration Restriction Act of 1901 and implemented a dictation test that could be administered at the discretion of government officials to any potential immigrant. This test was often delivered in a language that was unfamiliar to the immigrant and thus became an effective means for controlling immigration. Race-based nationalism and an unfounded fear of being overrun by the burgeoning Asian populations to the north remained the driving forces behind the White Australia Policy for the better part of the twentieth century until the policy was officially dismantled in 1972.

the region was a defining feature of Oceanic globalization prior to 1940. Finally, Asian migration to Oceania coincided with capitalist interventions in agriculture and the developing global trade in commodities.

Initial migration to Australia and New Zealand largely comprised convict transportation that lasted until the mid-nineteenth century. Convict transportation was replaced by assisted labor migration aimed at developing trade in commodities that included wool, gold, and wheat against the backdrop of “white” settlement. Although the assisted migration policy was racially exclusionist and favored British settlement, European migration was permitted. Subsequently, the 1901 Immigration Restriction Act (Australia) meant that non-Europeans could only enter on a temporary basis.

Continuing labor shortages had earlier led to importation of South Sea Islanders, mainly from Melanesia, as indentured labor to work in the

sugar plantations of Queensland. Most of them were officially repatriated in 1906–1908, following passage of various exclusionary regulations.

Chinese and Indian labor migration to Oceania was an integral dimension of the global trade in commodities. Chinese migrants entered a much more diversified and open labor market in Australia and New Zealand, initially as indentured workers under the credit-ticket system or as free immigrants who paid their own passage. They were also more mobile than Indian immigrants. In 1857, there were 26,000 Chinese miners on the Victorian goldfields, representing 32 percent of the mining population; however, their systematic exclusion under the Australian (and similar New Zealand) Restriction Acts resulted in the percentage of Chinese falling from 0.78 percent in 1901 to 0.16 percent of the population in 1947. In New Zealand, Chinese numbered 5,004 in 1881, but by 1916 their numbers had declined to 2,147.

Indian labor migration to Melanesia (Fiji) was consistent with Britain’s annexation of Fiji, imperial domination of India, and these colonies’ specific economic roles in the greater British empire. The migration of indentured Indian laborers to Fiji from 1879, to work for the Australia-based Colonial Sugar Refining Company, was a direct consequence of prohibition against the employment of indigenous Fijians as wage laborers. By 1916, some 60,000 Indians had been shipped to Fiji on five-year contracts. Many acquired land and stayed on, and by the 1940s Indians surpassed the Fijians and this trend was reversed only in the 1980s. Relations between Indians and Fijians were strained and fear and contempt between the two groups hindered assimilation in Fijian society. After independence, many educated Indo-Fijians left Fiji, and became “twice” migrants, mainly in Australia and New Zealand.

The colonial presence in Micronesian Oceania was initially identified less with plantation agriculture and more with strategic interests and resource extraction. At the turn of the century, Germany took over control of the Marshall Islands and acquired the Carolinas from a moribund Spanish administration, largely to facilitate the activities of a German company. Labor was sourced internally. After the Japanese took over the islands

in 1914, sugarcane cultivation was started and commercial fishing also became important.

Immigration to the main islands in Polynesian Oceania (Samoa and Tonga) was dominated by geopolitical considerations. In 1899, Germany took over Western Samoa while the United States assumed control over Eastern Samoa. From 1914, New Zealand occupied and administered Western Samoa under a mandate from the League of Nations.

Jewish Diaspora

Anti-Semitism, widespread discrimination and persecution, and little recourse for social mobility forced members of many Ashkenazi (German Russian and East European Jews) and Sephardic (Spanish, North African, and Middle Eastern Jews) Jewish communities to migrate in the first half of the twentieth century. Immigration quotas established in many host countries during the interwar period and during World War II, however, forced many Jewish migrants to seek other options. Many of them were unable to leave German-occupied Europe and became victims of the Holocaust despite the efforts of their fellow Jews in the United States and Britain.

Major events ranging from pogroms in late tsarist Russia to the Dreyfus Affair in the French Third Republic in the late nineteenth and early twentieth centuries convinced many Jews to emigrate. Many Ashkenazi Jews, following prior patterns of migration, immigrated to the United States, Canada, and Australia in growing num-

bers in reaction to the surge in anti-Semitism in Europe. In addition, Sephardic Jews in the Ottoman empire were also migrating to the Americas in greater numbers in the wake of World War I, driven by economic factors and the lack of social mobility granted in Ottoman society and in the Balkan successor states. Both Jewish groups also immigrated to the British Mandate of Palestine (after 1919). Jewish communities already established in the host countries, most notably in the United States, Canada, Australia, and South Africa, welcomed and assisted the newcomers with financial and institutional assistance. Furthermore, the development of the Zionist movement under Theodor Herzl (1860–1902) in the Habsburg empire opened the possibility for East European Jews to migrate to the Ottoman dominion of Palestine.

The outbreak of World War I cut off any immigration routes for European Jewry. However, the Jewish Diaspora communities fought for their respective host countries for both the Entente (Britain, France, and Russia) and Central

➤ INTERWAR ASYLUM—JEWS AND THE DOMINICAN REPUBLIC

In the 1930s when most of the world closed its borders to large-scale immigration from Europe, specifically Jewish migrants attempting to escape National Socialist anti-Semitism in Germany, the Dominican Republic was a rare exception. In 1938, Dominican Republic dictator Rafael Trujillo opened his country to 100,000 Jews seeking asylum. However, fewer than 1,000 Jewish migrants took up this offer, with most of them choosing to settle in the coastal community of Sosua. Trujillo, notorious for his massacre of approximately 25,000 Haitians in 1937, avidly encouraged Jewish immigration, as he felt that they would bring valuable skills that his country desperately needed as well as racial attributes to Europeanize Dominicans. While Jewish immigration to the Dominican Republic was comparatively small, it still signified an exception from the closed borders of the United States and the British Dominions, which had historically been open to large-scale Jewish immigration prior to World War I.

—Abraham O. Mendoza

powers (Germany, Austria-Hungary, and the Ottoman empire). British, ANZAC (Australia and New Zealand Corps), Canadian, South African, and American forces included Jewish officers and soldiers. The German and Habsburg forces also included large numbers of Jewish soldiers. Both sides were cognizant of the importance of Jewish communities within their countries and their support of the war effort. British foreign secretary Arthur Balfour had this in mind when he issued the classified Balfour Declaration, which suggested the possibility of a Jewish homeland in Ottoman Palestine to ensure the support of British (and Entente power) Jewry.

The end of World War I and the subsequent interwar period (1919–1939) were characterized by strict immigration quotas and growing xenophobia in many of the formerly hospitable host countries for Jewish immigration. In the United States, Canada, Australia, New Zealand, and South Africa, immigration legislation was put into place that set quotas for East European and Asian immigration and showed preference for migrants from Britain of “Anglo-Saxon racial stock.” Much of this legislation was aimed at preventing the entry of Jews and Slavs and ensuring the continued migration of superior Anglo-Saxon “racial stock” but was also due to fears of Bolshevism, which was associated with Jews in many of these countries. Furthermore, the newly acquired British Mandate over Palestine restricted Jewish immigration to small numbers, which hampered the ambitions of the Zionist movement. Nonetheless, many determined Jewish settlers entered the region illegally. Many Jews who had formerly sought refuge in these countries made do with migration to Latin America, mostly in Argentina and Brazil, until those places also instituted immigration quotas.

The establishment of the overtly anti-Semitic National Socialist movement in Germany in 1933 drove many German Jews to seek asylum elsewhere. However, strict quotas established in host countries limited their ability to leave the Third Reich. In spite of the clamor of established Jewish communities in host countries to assist downtrodden fellow Jews in Germany, political and economic considerations were given a higher priority than humanitarian

considerations. Furthermore, anti-Semitic and racist attitudes also led many politicians and officials to fear that too many Jews would migrate if given the opportunity. The few open spots available for those seeking asylum led to long lines outside of foreign embassies in Berlin, with many hoping to secure a spot. Wealthy Jews were typically able to secure a spot, while their less-wealthy cohorts were abandoned to the discrimination instituted by the Nazi state in the form of the Nuremberg Laws of 1935.

During World War II, millions of European Jews found themselves at the mercy of the Third Reich. The *Einsatzgruppen aktions* (massive shootings of Jews), massive starvation in the ghettos, and the “final solution” (destruction of Jews in death camps), which characterized the Holocaust, led to the estimated deaths of 6 million Jews in Europe. The Jewish Diaspora worked actively to bring the slaughter of their fellow Jews to the attention of the Allied Powers, but such demands mostly fell on deaf ears. Most of the political and military leaders of the United States, Britain, and the Soviet Union felt that the defeat of the Axis Powers was a higher priority than the destruction of the Nazi death camp infrastructure. With the liberation of the concentration and death camps by Allied forces in 1944–1945, many surviving Jews were placed in Displaced Persons (DP) camps, which were interim facilities. Large numbers of these DP Jews chose to go to Palestine, the United States, Australia, New Zealand, and Canada, with smaller numbers desiring to return home to Germany and eastern Europe. With the building outrage caused by the realization of the extent of the Holocaust, asylum was granted in North America and Oceania to many Jews. However, Palestine was closed to Jewish immigration by British authorities, sparking large-scale illegal immigration in the immediate postwar period.

■ Introduction: Domestic Migrations

The domestic migrations of people from rural to urban regions rapidly accelerated throughout much of the world from 1900 to 1945. Technological and scientific innovations in agriculture as well as rapid industrialization in various world regions prompted these internal migrations. In Europe, North America, and Oceania, higher wages and the promise of social mobility available in urban centers continued to attract migrants from rural hinterlands, following a long-term pattern from the prior century. Moreover, in the context of the two world wars, war mobilization and the growth of related industry also increased urbanization during this period. To a lesser extent, urbanization increased in Latin America, Asia, and Africa—regions which had retained a large portion of their population in rural areas as a result of their extraction industries and agriculture. Migration to the cities in these regions would vastly accelerate after 1945.

—*Abraham O. Mendoza*

Migration in Africa

During the colonial era, migration in Africa was characterized by an attempt to perpetuate the population distribution that existed when the European powers took over the territories, which were characterized by an artificial creation of boundaries separating many ethnic groups in between the newly established political entities.

Permanent migration within the African continent was discouraged by administrative policies. However, some important movements took place across international frontiers, in particular those of the Mossi and Hausa traders across French areas to the Gold Coast administered by Great Britain. In addition, seasonal migrations were avoided by a high legal tax that foreign farmers had to pay. Moreover, communication and transportation networks were developed within each colonial territory (from the interior to the coast) and displayed a pattern of

discontinuity with other regional frameworks (e.g., those crossing the Sahara). Separate currency systems utilized by the different colonial powers in Africa also made it more difficult for migrants to move to a different colonial system. In addition, customs fees discouraged potential migrants from crossing frontiers or increasing the length of stay of those who had migrated.

A further restraint to migration was the educational system. At the secondary level the system concentrated students in a few centralized regional institutions, such as William Ponty in Dakar for the French African territories. However, at the university level, European schools were emphasized. For the urban elite, this sort of educational migration was longer than that of a laborer.

In all, the effect of taxes on migration was more widespread than that of the educational systems. Head taxes were introduced, which induced people to migrate to centers where they could find jobs. Some men migrated in order to be able to pay taxes, while others migrated to avoid paying taxes. Thus, economic pressures (to earn money in order to pay the dowry or taxes), the desire to escape from the direct authority of chiefs and elders, and avoiding recruitment were the major explanations of African migration. In fact, colonial administrations disliked migrations because the control of migrants, the collection of taxes, and the recruitment of laborers were rendered difficult.

Migration increased gradually during the colonial era, with various types of temporary and permanent migrations. During the first four decades of the twentieth century, three categories of temporary migrants existed: the peasant-laborer who came to town or to a cash crop area for some time and then went back home; the educated African who migrated as a student and later as a government, mission, school, or commercial house employee (certain trading ethnic groups—Hausa, Dioula, and Wolof—had come to engage in roles close to that of the educated elite); and non-African elites, such as European officials working in administration, commerce, schools, and missions, and Indian merchants

within the East-African British territories who migrated temporarily.

Permanent migration was less multifaceted. Permanent urban skilled laborers had emerged who were often second-generation immigrants. Some of them left schools and accepted urban clerical jobs or began to work in the cash crop regions as farmers and traders. Often these migrants had settled in cities of the same country as their village of origin. There was also a new permanent rural middle-class settlement in cash crop areas. The ancestors of these people had not lived in the same rural areas. Examples were migrants to European farms and plantations in settler colonies such as Kenya, parts of German East Africa, Rhodesia, Angola, and South Africa. These colonies could only be developed with huge rural-to-rural migrations. Another group was that of Syrian-Lebanese origin working as merchants and who intermarried with local populations. A last group came from West India and merged into the East African urban elite. Famines in southern and eastern Africa at the turn of the twentieth century also encouraged migration. For example, up to 1920 Mozambique lost 100,000 inhabitants to the region of the current Malawi, where refugees found work as laborers building railroads or working on plantations.

Migration also affected the age-sex balance within the African colonies, and thus it influenced the social tasks attributed to various groups. Toward the beginning of the colonial era, women rarely participated in migration movements. At the same time, low salaries and dwellings built for young bachelors did not allow the family to live in towns. As a consequence, in immigration regions there was an extreme excess of men, and in emigration regions there was an extreme excess of women. One of the many consequences of this reality was the appearance of prostitution and homosexuality. In many towns, there were only 100 women per every 130 to 250 men; in the South African miner towns, the African population consisted even of 93 percent men in 1910.

Over the long run the patterns of migration changed. Since the colonial economy could not find enough men, women and children began to

be employed at lower salaries. Migrants no longer responded to immediate pressures for cash, and the rural economy became dependent upon the national economy and on the money that the migrants sent home or brought back. As unemployed youths decided to leave for urban centers, labor migration became a means of coping with a surplus rural population. The individual return migration also led to the creation of new desires, such as buying new commodities. Yet until World War II, this influence was rather small in rural regions.

Overall, urban centers attracted migrants because of their administrative, commercial, and sometimes industrial activities. The immigrants concentrated in certain types of jobs and belonged to certain status groups. They knew economically competitive situations and created ethnoprofessional groups. These ethnic associations influenced later modern political organizations so that colonial administrators blamed migrants. Migration was seen to induce unemployment, destitution, and crime. An increasing number of children born in towns returned with their migrant parents to villages that they considered a new phenomenon. Migratory movements widened the political perspective of more and more people. Even if much migration was short-term, migrants were brought into contact with new ideas that after World War II threatened the colonial power system and the relations to traditional political rulers. Migration was thus a phenomenon that contributed to the transformation of African societies.

Migrations within Asia

The period from 1900 to 1945 in Asia was characterized by colonialism, modernization, and urbanization, all of which provided the continued impetus for migration within the region. Intraregional and interregional mobility were widespread, and some migrant communities, such as the Koreans in Japan, reached record numbers during this time. Aside from a relatively favorable physical geography, cross-border migration took many forms in response to the social, economic, and political conditions in these peoples' countries of origin and in the receiving states. Notable cross-border migrations included labor, military, student, and trade migration as well as the resultant chain migration.

Much of Asia at the turn of the twentieth century was under foreign control. With the exceptions of Thailand and Japan, the rest of Asia was invariably under direct and indirect control by the major Western powers. European expansionism and capitalism created large-scale plantations in colonies that required constant flows of laborers, many of whom were indentured until 1920. The opening of treaty ports to foreign control advanced the Chinese coolie trade. South Asians from Madras migrated en masse to British Malaya to work in the rubber estates from the early 1900s to the 1920s. Indian labor filled colonial administrative positions in Burma, forming its middle class until 1945. Although having a long history of migration, the labor demands in Southeast Asia pushed many Chinese peasants and fishermen to work in the Dutch East Indies and in British-owned mines and plantations. Chinese migrants were concentrated in mining districts of the Federated Malay states.

Japan was the only non-Western imperial power in Asia until 1945. Control of Korea, Taiwan, and Manchuria led to migration within these areas as well as into Japan. Recruitment, both private and government initiated, of Korean labor responded to the structural requirements of certain Japanese industries such as construction, mining, and glass, leather, and fertilizer manufacturing. Three million Koreans migrated to Japan from 1910 to 1945. By 1945, there

were 28,000 Taiwanese in Japan. Another 1.5 million impoverished Korean peasants moved to Manchuria between 1931 and 1945. In the 1910s and 1920s, Chinese migration to Manchuria rapidly increased. In 1921 more than 1,000 Chinese longshoremen were in Japan, but their continued presence, together with the Koreans, caused local resentment. These tensions culminated in the mass killings of an estimated 6,000 Koreans and 700 Chinese workers by the military and disgruntled citizens in Tokyo and Yokohama after the Great Kanto earthquake in 1923. Japanese peasants also were encouraged to migrate to Manchuria, and by 1939 their numbers reached 1.1 million.

Military migration occurred under British colonial rule. Punjabi—members of a religious minority in India—became known for their martial skills and loyalty during the Sepoy mutiny and were vigorously recruited for the Gurkha regiment of the British Army and as security forces in colonial posts. About 150,000 Sikhs were enlisted in the army by the time of World War I (1914), and in 1939 there were 774 Sikhs in the Hong Kong police. After the dissolution of the Sikh contingent, about 15,000 stayed in Malaya. Nepalese hill men also served as Gurkhas, numbering more than 50,000 during World War I and fighting alongside the Allied forces in World War II. About a third of them returned to Nepal after the war.

Modernization and urbanization contributed to domestic migration within the region. The rise of new urban centers and portals of economic exchanges linked the local and regional with the outside world. The construction of rail systems and canals facilitated travel and trade, as in the case of Jat Sikh peasants and independent immigrants from South Asia to the Far East. Land reclamation projects in Nepal from the 1890s to the 1930s allowed Indian zamindars (landlords) to possess land in the unpopulated plains on the Midwest and encouraged the migration of tenant farmers. Rising costs of rent and taxation pushed many Nepalese to migrate to nearby Indian highlands and cities to work. In the 1901 census, 200,000 Nepalese resided in India. In Malaya, the expansion of rice cultivation witnessed the entry of Indonesians

into farming districts comprising about 15 percent of the total population since 1911.

The precipitation of modern ideas was nowhere more visible than in the area of education, where many students were sent abroad to study. In 1903, about 1,000 Chinese students were enrolled in Japan, and many were later involved in anti-Qing revolutionary activities. Pursuing higher education outside of China became a new form of migration strategy. Students of different Asian ancestry were admitted into the newly founded Manchuria Nation Building University in 1938.

The most common form of migration was chain migration, particularly of the Chinese and South Asians following the lead of male family members already settled in the country of destination. Increasing numbers of women, along with their children, started joining their husbands overseas. For example, Chinese women in Singapore reached 45 percent of the total Chinese population from 1935 to 1939. Economic opportunities and domestic political unrests prompted many to leave China. Different Chinese ethnolinguistic groups emigrated this way to an already established trading network in Southeast Asia. Massive Chinese migration to Thailand occurred in the 1920s, with 70,000 to 140,000 migrants a year. In the 1930s, the Chinese consisted of more than 70 percent of the population in Singapore. South Asians, on the other hand, also have a tradition of chain migration based on religious and economic ties with China and Indonesia. Some South Asian communities have long left their native places because of persecution and brighter opportunities abroad. The Parsis, for example, followed an ancient migration religion and often moved away from a hostile environment. Other South Asians followed in the footsteps of traders and independent migrants who successfully settled in Southeast Asia. In Singapore, Indians took advantage of the common British governance to look for employment.

Migrations within Europe

Between 1900 and 1945, millions of people voluntarily moved within Europe to improve their economic standing and to escape the ravages of war. In addition, forced migrations during two global military conflicts included the relocation of conquered civilians to war-production areas and the herding of Jews into concentration camps. The first four decades of the twentieth century also witnessed the general transformation of unhindered, voluntary, and seasonal labor migrations to state-regulated and state-restricted movements.

At the beginning of the twentieth century, migrations within Europe reflected the traditional nineteenth-century movements of temporary or seasonal workers from rural southern and southeastern Europe to central and western European fields and factories. World War I, however, changed these historic migration patterns. Migrations to overseas destinations decreased dramatically, and return migration temporarily increased as thousands of people went home. As countries removed men from their labor force in order to man the trenches, governments actively sought or coerced foreign laborers. For example, France maintained its traditional source of migrant labor from Spain and Italy but also recruited laborers from new sources such as Greece, North Africa, and China. At the same time, Germany denied Polish and Russian seasonal workers the right to return home, while the imperial government deported Belgian and Dutch civilians and relocated prisoners of war in order to coerce and utilize the labor of over two million foreigners during World War I.

The military conflict also created a refugee crisis as millions of people tried to escape war-ravaged areas. Over one million refugees left Belgium and France during the war in order to move southward and westward. Historians estimate that five million people became refugees on the eastern front of the war. Though the fighting ended with the armistice of November 1918, the refugee crisis continued. During the war, in addition to the persecution and genocide of Armenians in Turkey, as many as two million were deported and, often after long marches, forced into relocation camps. The 1917 Russian Revolution resulted in hundreds of thousands of exiles and refugees primarily moving to central Europe, while the transfer of Alsace-Lorraine to France and the construction of new states, such as Poland, not only contributed to the return migration of conational ethnic groups but also turned one million Germans into refugees.

The period between World War I and World War II marked a change in human movements as governments began to more intensely regulate and control migrations in order to protect local workers. German officials reduced the length of working visas to one year and issued permits to foreign laborers only if German workers did not fill positions. The Italian government restricted the migration of labor within Europe in order to preserve the national character and encouraged settlement in Ethiopia to solidify imperial control. By contrast, the French state, more than any other European country, actively recruited laborers through bilateral agreements with Poland, Spain, and Italy to rebuild the war-torn areas and work in agriculture. Adoption of immigration limits in the United States (1921 and 1924) drastically reduced transatlantic migrations from Europe. During the international economic crisis of the 1930s, however, thousands of migrants returned and stayed at home. Western European countries, including France, a traditional immigration country, closed their borders to labor migration. The 1920s and 1930s also witnessed a general movement of populations from the rural to the urban areas. Following the establishment of the Irish Free State (1922), England became the destination of choice for many Irish migrants, despite persis-

➤ MIGRATIONS IN THE BALKANS

The forced migration and segregation of nearly two million Greeks, Turks, Romanians, and Bulgarians between 1912 and 1928 represents an important aspect of migration history in early twentieth-century Europe. The First and Second Balkan Wars (1912–1913) resulted in the fleeing of nearly half a million Muslims from the Balkans to Turkey and treaties that exchanged minorities in order to create more ethnically homogeneous societies in the region. Greece and Turkey signed a similar agreement ending the Greek-Turkish War in 1923, mandating the resettlement of Greeks and Turks to their respective countries. The forced separation of ethnic groups in southeastern Europe did not alleviate future conflict but instead worsened it, as segregation intensified ethnic stereotypes and hatred.

—Petra DeWitt

tent prejudices. Irish women in particular used this opportunity to move to the urban areas of England to work in factories and offices. At the same time, Italian migrants, who faced emigration restrictions, also moved more frequently from rural to urban areas in increasing numbers, entered white-collar employment, and stayed permanently.

Political events also encouraged migrations during the 1920s and 1930s. The rise of fascist governments in Spain, Italy, and Germany contributed to the migration of political exiles and undesirable ethnic groups. Jews represented the largest segment of these oppressed people, as Poland, Romania, Hungary, Austria, and Germany actively persecuted them. Historians have estimated that over 400,000 Jews sought refuge in France, the Netherlands, Switzerland, England, the Americas, and Palestine, although they faced anti-Semitism and bureaucratic restrictions. The beginning of World War II virtually ended the voluntary migration of Jews; instead, the German government relocated Jews into ghettos and concentration camps.

World War II contributed to the migration of more people than any other event during the first half of the twentieth century. Masses of people fled as German armies overran Poland,

the Netherlands, Luxembourg, Belgium, and France. The Soviet Union had forcibly relocated Poles, Ukrainians, and White Russians after its Non-Aggression Pact with Germany in 1939. Germany also intensified the expansion of its *Lebensraum* (living space) into eastern Europe by relocating or deporting Slavic people and resettling ethnic Germans on incorporated and conquered land. German advances into south-eastern Europe and the invasion of the Soviet Union in 1941 further uprooted millions of people. The German war government forcibly relocated many of these displaced persons into labor camps, and they were then used in the war effort.

As the war ended, masses of people, including refugees, forced laborers, and prisoners of war, returned home. Following the war, Poland, Czechoslovakia, and Hungary—with the approval of the Allied Powers—expelled 12 million *Volksdeutsche* (ethnic Germans), including those who had lived in eastern Europe for generations, and repatriated displaced persons to the former Reich territories.

Legacies of the migrations within Europe during the first half of the twentieth century include the establishment of the Jewish State of Israel in 1948. State regulations of migrations also intensified further as Europeans not only dealt with unprecedented internal movement but increasingly confronted international migrations brought on by the decolonization movement of the 1920s and the collapse of European imperial empires at the end of World War II.

Domestic Migrations within the Americas

From the beginning of the twentieth century to the end of World War II, much of the internal migration within the Americas is characterized by the movement of rural populations to urban industrialized regions and major cities. In North America much of the internal migration was from Canada to the United States in addition to large flows of people from the U.S. East Coast and from the South to the West, given the economic fluctuations of this period. Furthermore, Caribbean immigration to the U.S. East Coast as well as Florida was also quite common in this period. South American internal immigration was characterized by the migration from the countryside to the bustling city centers as countries such as Argentina, Brazil, and Mexico experienced modernization and industrialization during this period. The Mexican Revolution (1910–1920) also displaced many northern Mexicans into the southwestern United States, many of whom were later deported back in the 1930s during the Great Depression.

Between 1900 and 1914 migratory patterns in the Americas were primarily characterized by immigration from Europe. European immigrants in the millions entered the United States and Canada. Significant numbers of immigrants to Canada went there due to the fact that they were unable to enter the United States, which they later were set on doing after spending a brief sojourn there. Neo-European Latin American countries (those with large concentrations of European-descended populations) such as Argentina, Brazil, Chile, and Cuba experienced a large influx of European immigration, with lesser numbers migrating to the primarily mestizo countries of Mexico, Colombia, Venezuela, and Cuba. Only minute numbers of individuals migrated from one Latin American country to another. The outbreak of World War I in 1914 ended any significant emigration from Europe.

From the 1930s to the 1940s, internal migration in the form of rural to urban outmigration was occurring throughout the Americas en masse. Rapid industrialization and urbanization in many American cities encouraged peasants, farmers, and sharecroppers to leave their professions

and move to the city to make a living, drawn by higher wages and a more exciting city life. Large numbers of rural denizens moved to the major cities of the East Coast and the industrial cities along the Great Lakes regions. In particular, black Americans migrated from the Jim Crow South to the northern United States in pursuit of better job opportunities from World War I through World War II in what is known by historians as the Great Migration (1910–1940). Large urban populations of blacks grew in many U.S. cities such as New York, Philadelphia, Detroit, Los Angeles, and Oakland due to the large amount of employment created by war industries, particularly during World War II. The Immigration Act of 1924, which cut off emigration from eastern and southern Europe due to xenophobic attitudes in the interwar United States, also led to active labor recruitment of black Americans. The Great Depression of the 1930s also drove many dispossessed farmers (known at the time as Okies) from the Midwest and the Southwest to California, Oregon, and Washington. While many of these Dust Bowl migrants sought work in agriculture, large numbers of them were eventually absorbed into war industries in the Pacific states with the outbreak of World War II. In addition, Canadian internal migration from the eastern provinces to the western provinces, principally to British Columbia, also increased during this time due to the development of agriculture, mining, and other primary industries.

In the various Latin American states, the increasing poverty of the Great Depression years and the constricting social system of patron rule by caudillos (strongmen) in the countryside drove many to search for opportunities in the cities. The relatively more egalitarian cities offered former farmers opportunities in industrial and service professions. Major Latin American cities such as Mexico City, Buenos Aires, and Rio de Janeiro drastically grew in size. Furthermore, as these states were cut off from a steady supply of European immigrants due to the world wars, it was necessary for the state to encourage internal migration for the purpose of sustaining a growing economy, even amid the Great Depression of the 1930s.

Wars and economic dislocation also drove many Latin Americans to seek their fortunes in other adjacent countries. The Mexican Revolu-

➤ THE AMERICAS IN WORLD WAR II— CONTINENTAL SOLIDARITY

World War II unleashed a massive internal migration within the Americas, with individuals searching for better economic opportunities as economies across the Americas mobilized for a war on two global fronts. In addition, many American countries, not just the United States and Canada, contributed to the aggregated American war effort. Members of the Pan American Union (later the Organization of American States) formed an alliance for the mutual defense of the Americas in Havana in July 1940. Twenty-one American foreign ministers (from the United States, Mexico, Brazil, and other Central and South American states) signed the Declaration of Reciprocal Assistance and Cooperation for the Defense of the Nations of the Americas to coordinate their resources and military forces for the global two-front war. Furthermore, to make up the loss of American workers in agriculture now working in defense industries, the U.S. government made a deal with the Mexican government for the use of guest workers (*braceros*), which brought thousands of Mexican farm laborers into the U.S. Southwest. Economic arrangements for nitrates were also made with countries such as Chile to ensure the constant supply of these for wartime needs, fostering economic continental integration for war production.

—Abraham O. Mendoza

tion and the need for farmworkers in the United States due to the labor scarcity created by World War I prompted many Mexicans to migrate to El Norte, particularly to the U.S. Southwest. Economic fluctuations and xenophobia in the interwar period would lead to many of them being deported back into Mexico. Nonetheless, guest worker programs and a need for a readily available cheap labor pool led to a continued flow of Mexican immigrants into the United States during World War II. Much like Mexican immigrants, Caribbean immigrants, such as Puerto Ricans, Jamaicans, and Cubans, migrated to U.S. eastern cities (particularly New York City) and Florida seeking employment as ticket laborers (indentured temporary workers) in agriculture or in the lower echelons of the service industries, as many of these jobs were undesirable or

unfilled due to the draft and war mobilization. In particular, black migrants from the British Caribbean took advantage of the quota for Britain created by the U.S. Immigration Acts to enter in large numbers, which U.S. authorities had not intended when they implemented the act in the hopes of attracting white Britons.

The Great Migration—African American Migration within the United States

Trapped in a system of debt peonage, robbed of civil rights, deprived of voting rights, and subjected to a rising trend of lynchings, African Americans began escaping the segregated Jim Crow South in the 1890s. Over the next 20 years the slow, steady stream of black migrants traveled to southern and border cities such as Atlanta, Baltimore, Louisville, Memphis, New Orleans, Richmond, and St. Louis before moving north. Following their arrival in the urban areas, African Americans took low-paying jobs, working as janitors, laundresses, maids, housekeepers, waiters, and porters.

World War I was a watershed event for the African American community, as it was for people all around the globe. As immigration from Europe ended and the military expanded, the United States turned to African Americans to fill the ranks of the industrial workforce. Recruiters scoured the South for those eager to leave on the promise of steady work in the North. Well-circulated newspapers such as the *Chicago Defender*, which printed a famous editorial on May 15, 1917, exhorting African Americans to leave the South, also carried the message. The devastation that floods and boll weevils took on cotton left many southern farmers—black and

white—with little alternative but to accept a guaranteed job that was offered to them. Southern business interests unsuccessfully attempted to coerce black laborers from departing. By 1919, as many as one million African Americans had moved north to Chicago, Cleveland, Detroit, New York, Philadelphia, and Pittsburgh, among other cities.

Much to their disappointment, African Americans found that the urban North was no more hospitable in many ways than the rural South. Restrictive covenants on housing, racially motivated zoning laws, unofficial segregation, and vigilante violence kept African Americans confined to rapidly decaying urban ghettos and their facilities. Often, the buildings were of poor quality and lacked indoor plumbing and heating. Garbage was often piled high in the streets, and entire neighborhoods stunk from rotting trash, poor sanitation, and outhouses. As more people crowded in, even the most decrepit housing commanded premium rates. Concerned about protecting their neighborhoods, whites outside of the ghettos met even the most harmless excursions with violence, resulting in a spate of serious race riots in 1917, 1919, and 1921. Conflict resulted from concern not only over neighborhood control but also over jobs. Many white veterans assumed that they would get their jobs back when they returned from the war. On the other hand, many African Americans felt that having proved their loyalty to their country, they deserved to be treated as equal citizens.

Throughout the 1920s and 1930s the exodus north continued, particularly as a deepening economic crisis and mechanized harvesting of cotton made sharecropping and farmwork even more precarious as a livelihood. The Great Depression might have slowed the migration slightly, as unemployment of blacks greatly exceeded that of whites, but President Franklin D. Roosevelt's New Deal unintentionally revived it. Federal assistance programs, such as Aid to Families with Dependent Children, paid more money in most northern states than in the South. The Agricultural Adjustment Act provided large subsidies to white rural landowners, but the black tenant farmers received no money, and many were kicked off their land as a result. Finally, federal money for public housing was used to im-

prove conditions inside the ghettos and create more space by making the buildings taller.

World War II further accelerated African American migration northward, as hundreds of thousands of additional black migrants moved north to find work in war industries and thus help build the so-called arsenal of democracy. The African American population of Chicago, for example, swelled 77 percent, and that of Los Angeles doubled. Many urban areas in the North experienced similar rates of growth. Once again, adjustment was difficult, and there were numerous race riots in 1943.

The Great Migration had a number of important effects. First, it led to the flourishing of a uniquely black culture. In the movement labeled the Harlem Renaissance, artists, musicians, poets, playwrights, and novelists captured the frustrations, disillusionment, and occasional victories that African Americans experienced during the Great Migration. Over time such artistic forms bridged the racial divide and became part of the wider American popular culture. Second, African Americans developed a political power that they lacked in the South. The right to freely exercise the franchise in the North allowed for the election of African American representatives in nearly a dozen states by the end of World War II. During the 1920s, most of the African American political thought was expressed in the Black Nationalist movement of those such as Marcus Garvey and his Universal Negro Improvement Association. During the 1930s African Americans moved more into the political mainstream and began to vote in large numbers for the Democratic Party. By the 1936 presidential election, northern urban African Americans had become an important Democratic Party constituency.

—Gregory J. Dehler

➤ 1943 RACE RIOTS IN THE UNITED STATES

On June 25, 1941, President Franklin D. Roosevelt issued Executive Order 8802 prohibiting racial discrimination in hiring practices among industries that received U.S. government contracts. The purpose of the order was to grant African Americans some access to skilled high-paying jobs, which would allow them to share in the wartime prosperity. Roosevelt's order, however, could not stop racial tension. Relocation by hundreds of thousands of blacks and whites, competition for jobs and housing, the incidence of hundreds of small acts of racial violence nationwide, and wartime nervousness combined to trigger three significant race riots in the summer of 1943. The first began in June in the shipbuilding facilities of Beaumont, Texas. Five days later, a massive race riot that left over 20 dead and 1,000 wounded rumbled through Detroit. Six weeks later, a riot in Harlem destroyed hundreds of white-owned stores in black neighborhoods.

■ Introduction: Ethnic and Forced Migrations

The first half of the twentieth century witnessed significant demographic shifts throughout the world with a number of underlying causes, including the search for jobs and labor supply, ethnic migrations to rapidly in-

dustrializing countries, forced population displacements, and war. International migration was generally voluntary and unregulated until 1914, the year when World War I began. The liberal spirit of the times up to the outbreak of the

➤ 1915: THE DEPORTATION OF ARMENIANS FROM THE OTTOMAN EMPIRE

A topic that has stirred up much scholarly and political-legal controversy, the deportation of a massive number of Armenians from various provinces in eastern Anatolia is one of the many severe incidents at the time of World War I. On the grounds that several Armenian groups, otherwise Ottoman subjects, were collaborating with Russian forces at war with the Ottoman Army in a number of fronts in World War I, the Ottoman government made a formal decision to deport about 1 million Armenians from eastern Anatolia to Syrian inland, then under Ottoman rule. More than half of the deportees lost their lives en route. The political and scholarly debate hinges on the causes of these tragic losses. While some wish to qualify the events of 1915 as the first genocide of the twentieth century and attribute the deaths to a premeditated Ottoman design to systematically annihilate the Armenian population, others suggest that there is no evidence of such premeditation and that epidemic diseases, extreme poverty, famine, and intercommunal fighting account for lost Armenian lives.

—*Fethi Keles*

war encouraged free international mobility. Extensive emigration from the center and periphery of Europe to favorite destinations such as North America (including the United States and Canada) and Australia for better jobs and livelihoods characterized the prewar era.

In addition, the rapid growth of global capitalism, along with the implementation of imperial policies worldwide, accelerated the search for jobs and new locales for settlement. In Southeast Asia, this resulted in millions of Indians and Chinese becoming contract laborers on plantations and in rice fields and mines mainly in the Southeast Asian region but also in distant destinations including Latin America, North America, and European colonies in the Caribbean.

With the onset of World War I, the nearly universal liberal norm of free movement of people underwent a sea change. Combatant states went to great lengths to restrict emigration and immigration, passing laws and utilizing various

legal instruments (such as the passport) to that effect. These states further undertook systematic harassment and forcibly displaced foreigners in their lands who did not fit into idealized definitions of a nation-state. The waves of pogroms against Jews in Russia, for instance, led to massive Jewish immigration, most notably to the United States and Britain, among other countries. Even after the 1917 Bolshevik Revolution granted civic equality to Russian Jews, Stalin's moves to repress Jewish social life resulted in additional displacements.

As many new nation-states came into being upon the collapse of multiethnic empires, major population displacements, diasporas, and exchanges ensued. Hundreds of thousands of Armenians, subjects of the Ottoman empire, were deported from various Anatolian provinces on grounds of acting in collusion with the invader enemies in the war. The Ottomans' retreats in the Balkans led to the eviction of several thousand Turkish subjects from that region into Asia Minor.

Characteristic of the postwar period was the ascent of fascism across Europe. Hitler in Germany and Mussolini in Italy, for example, set out to create pure nation-states, declaring an ethnic core superior to all others in their respective countries. As a result, millions were on the move to find new homes or escape persecution. A protectionist international migration regime that chose to shut the doors to escapee newcomers to curb the effects of postwar economic stagnation and safeguard its respective domestic labor forces reinforced xenophobia and potentially contributed to the outbreak of World War II.

In addition, the question of stateless persons remained high on the international agenda after World War I and until the beginning of World War II. In 1922 the Soviets denationalized refugees fleeing communist Russia and invalidated their travel papers, stripping them of their status as members of the Soviet state. An effective solution came in the form of the Nansen passport, named after Fridtjof Nansen, the first high commissioner for refugees of the League of Nations. The passport allowed millions of displaced persons, mostly Russians, to travel legally and apply to other states for admission. This was one of

the earliest steps toward the institutionalization of the refugee regime internationally.

A legacy of this particular era has been the transformation of temporary controls and restrictions on emigration and immigration into permanent ones. The right to regulate the movement of people came to be seen as an exclusive right of state sovereignty, thus paving the way for the forced migrations of the decades that followed.

Bonded Labor

The end of slavery throughout much of the Western world in the late nineteenth century, beginning with its abolition throughout the British empire in 1833 to its abolishment in Brazil in 1888, ended a centuries-old system of forced labor. However, the need for labor throughout much of Europe's colonial domains necessitated another source of workers. British colonial authorities in India and China established linkages with local labor recruiters and began to export large numbers of indentured servants overseas. While mostly associated with the British empire, French, German, and American businesses with foreign investments in Latin America, sub-Saharan Africa, Southeast Asia, and Oceania also recruited large numbers of both Indian and Chinese coolies as indentured servants. By the early twentieth century this system provided a substantial amount of the Chinese and Indian diasporas spread over much of the West Indies, sub-Saharan Africa, Southeast Asia, and Oceania, estimated to be in the tens of millions.

In the early twentieth century the unequal development of world regions subject to European economic and military hegemony, particularly India and China, led to the continuation of the practice of indentured servitude. The political and economic instability of India and China, not to mention large-scale famines, in the late nineteenth and early twentieth centuries made recruitment of indentured servants quite easy for European officials and their subaltern middlemen. Coolies were subject to mistreatment, abuse, and long hours. Committed to five-year contracts to work for a miserly wage, they faced

THE BRITISH ELECTION OF 1906— CHINESE SLAVERY

The legacy of slavery left a deep imprint in the consciousness of the British electoral politics. The abolition of slavery in the British empire early in the nineteenth century, due to economic and moral arguments engaged through public debate, led to distaste for coerced labor practices and the advocacy of free labor markets. The ubiquitous practice of indentured servitude throughout much of the British empire since the end of chattel slavery did attain the same level of notoriety for decades. However, the national elections of 1906 brought the issue to the fore of public debate, as the Conservative Party under A. J. Balfour supported the importation of Chinese indentured labor into the South African mining district of Transvaal. The British Liberal Party, under the leadership of Sir Henry Campbell-Bannerman, reacted with indignation at the prospect of sending "Chinese slaves" to work in horrible working conditions and be subjected to potential abuse by employers. This election marked the beginning of the end for the practice of indentured servitude, which was now present in the public sphere and openly debated as a topic of discussion in early twentieth-century Britain, albeit with both moralistic and racist arguments against indentured servitude.

—*Abraham O. Mendoza*

destitution and poverty that forced many of them into this unreasonable sale of their livelihoods. At the end of five years many of them found themselves bound due to debt or having nowhere to go with no money on hand. Wealthy Chinese businessmen also participated in exporting indentured servants through the practice of the credit ticket. The credit ticket bound a laborer to work for his employer for a specified period of time anywhere his employer demanded, typically overseas. These employers would typically work with European firms—with which they had a financial stake themselves—and recruit labor in this manner as their own personal coolies.

The end of slavery created a huge void in the labor demands of the West Indies' sugar plantation economies. With the prevalence of Chinese

and Indian indentured servants in the plantations of the East Indies (Indonesia), British authorities found it expedient to bring large numbers of such laborers into the Caribbean plantation colonies, such as Jamaica, Barbados, and St. Kitts. Furthermore, following the scramble of Africa in the late nineteenth century, British authorities also began to import large numbers of Indian laborers into its east and south African colonies. British South Africa used large numbers of Indian workers at diamond mines and other industrial and mining concerns, much to the displeasure of the local Boers. In fact, large Indian communities in Kenya and South Africa were established due to the large concentrations of Indian indentured laborers imported by British colonial authorities and businessmen. In the early twentieth century in both South Africa and India, Mahatma Gandhi led a fervent campaign against the abuses of the system of indentured servitude, marking the beginning of his career as a civil rights leader and Indian nationalist. Many of the servants who had gone to Africa remained there permanently, effectively becoming immigrants. The large-scale immigration of the Overseas Chinese in the early twentieth century—concentrated mostly in Southeast Asia, Oceania, and the Dutch East Indies—was also due to the increased use of bonded labor. Immigration exclusion acts ended the practice of indentured servitude from Asia in the United States and Australia, primarily due to racist and xenophobic concerns and fears of the so-called Yellow Peril rather than the abuses inflicted on such laborers by this peculiar institution.

In 1904 at the end of the Boer War, the lack of native African labor in the Rand mines of the South African Transvaal led to the large-scale importation of indentured Chinese laborers by British colonial authorities. However, the Boer population in the Transvaal was fervently opposed to this act, fearful that it would exacerbate the already volatile racial problems of South Africa. This issue led to the British electoral victory of 1906 in which the issue of Chinese slavery was central to the victory of the Liberal Party, a decision that led to the beginning of the end of the practice of indentured service throughout the British empire. However, at the

time more than 50,000 Chinese laborers had already entered the Transvaal.

World War I increased the need for indentured servants throughout much of the world for the purpose of mobilizing colonial resources, filling domestic labor shortages, and effectively utilizing the full manpower of the colonies to engage the Central Powers. It also led to the conscription of large numbers of soldiers, auxiliaries, and laborers for use at various battle fronts. The mobilization of the British empire for the purpose of war involved using large numbers of Indian troops and laborers in Middle East campaigns and Chinese laborers in the western front. This also introduced the practice of indentured servitude into Europe, where it had previously had little public display. Furthermore, many conscripted soldiers, auxiliaries, and labor battalions from India saw firsthand the vulnerability of their colonial British overlords to the destructive onslaught of war, sparking nationalist aspirations in many of them. With the end of the war, Chinese laborers were imparted with the responsibility of cleaning up the damage along most of the western front up to the end of the practice of indentured servitude in 1920.

Forced Migrations in the Soviet Union

"Forced migration" is a general term that refers to the involuntary movement of people away from their homes to other areas, whether domestic or international. This term is used interchangeably with the terms "displacement" and "forced displacement" and often implies the use of coercion or violence. Forced migrations in the Soviet Union during the period 1918–1945 were mostly imposed by the government. The

most important forms of forced migration were the expulsion of wealthy peasants from grain-producing areas of the Soviet Union from 1930 to 1933, the political purges of the 1930s, and the nationality deportations from 1941 to 1945. Human displacement in the Soviet Union during these decades also included semivoluntary migrations, such as forced relocation resulting from the change of regime in 1917 from tsarist to communist and wartime evacuations in the early 1940s. There also existed other forms of forced migration within the Soviet Union that involved fewer people at a time.

During the period 1918–1941 the Soviet government deported, imprisoned, or exiled its citizens based mainly on their class or on a variety of political factors, though ethnicity was also one of the important components. The first Soviet attempt at mass relocation included the deportation of 70,000 rebellious Cossacks from the northern Caucasus and 100,000 rebellious peasants from the province of Tambov in 1918. In the period 1929–1933 the Soviet government attempted to turn agricultural production into a collective and state-controlled enterprise in a campaign labeled “collectivization” by means of “collectivizing” peasants’ farms, tools, and livestock. As a result of propaganda and coercion advanced by the Soviet government, by June 1929, 1 million wealthy peasants turned their agricultural tools over to the government and enrolled in collective farms. But many more, estimated at 25 million, held back. To promote its campaign, the government confiscated property and agricultural tools and livestock from wealthy peasants, called *kulaks*, and deported 1.5 million of these peasants to Siberia and northern Russia between 1930 and 1933. Approximately 900,000 more kulaks were arrested and sent to prisons or labor camps in remote parts of the Soviet Union. Only class and perceived wealth were used to single out people for deportation in this campaign. Although in the 1930s the majority of peasant families joined collective farms under the state’s administrative control, the collectivization campaign resulted in massive forced human displacement, a decline in agricultural production, and enormous losses of livestock due to slaughter and neglect.

➤ SOVIET POLICY TOWARD JEWS

The cosmopolitan and international character of the Russian revolutionaries allowed many Jews to join the ranks of the Bolsheviks. Many historians suggest that this was perhaps due to the anti-Semitic nature of the Russian nationalism utilized by the tsarist regime that classified Jews as traitors to the Russian state. Prominent Jewish revolutionaries, such as Leon Trotsky, were ardent supporters of the Soviet cause. However, after the emergence of Josef Stalin in the Communist Party as general secretary, many of these Jewish revolutionaries were suspected as traitors to the Soviet cause. Many Soviet Russian leaders, along with Stalin, suspected Soviet Jews of having foreign proclivities and loyalties and thus being potentially capable of treason. In the Great Terror purges of the late 1930s many Jews were removed from positions of power within the Soviet regime, most notably Trotsky and Maxim Litvinov. Furthermore, Jews from Germany and occupied Europe were prevented from entering the Soviet Union as refugees. At war’s end, the Soviet Union took credit for the liberation of the Jews and other eastern Europeans from the yoke of Nazi tyranny. However, some Soviet Jewish survivors of death camps had the unfortunate fate of being shipped to the Gulag, as they were exposed to “bourgeois” institutions and thus were suspect in the eyes of Soviet authorities.

—Abraham O. Mendoza

In the mid-1930s the Soviet government staged two massive waves of human displacement, one presumably based on political factors and another based on class and ethnicity. In the 1930s the Soviet government arrested, prosecuted, and exiled or imprisoned millions of people in political purges, which culminated in a grand wave of arrests in 1937–1938 known as the Great Terror. The official explanation for these purges was an attempt to cleanse the Soviet territory of foreign spies and internal enemies. Hence, the overwhelming majority of these people were accused of being spies and saboteurs and were sent to prisons on charges of treason as “enemies of the people.” The prisoners were torn away from their homes and forced to work for the Soviet government in inhumane conditions. Many

prisoners perished; however, some historians believe that this free labor was at the core of early Soviet economic success. The chain of prisons, collectively known by the acronym GULAG, housed as many as 1.3 million people in 1936 and almost 2 million by 1941, according to official Soviet documents. However, historians still dispute the exact number of prisoners, especially since hundreds of thousands of arrested Soviet citizens were shot. Some scholars estimate the number of displaced people at between 10 million and 20 million. The number of prisoners continued to grow after the end of World War II until Stalin's death in 1953.

Besides political and economic relocations in the mid-1930s, the Soviet government decided to cleanse its borders of various ethnic diasporas as a preemptive measure to strengthen the Soviet frontiers. As a result, during 1935–1938, 70,000 Germans and Poles and 30,000 Finns residing in the regions of the Soviet Union's western border were deported to Siberia and Kazakhstan, along with some Estonians, Latvians, Kurds, and Iranians. In 1937, all 170,000 Koreans of the Soviet Far East were resettled to central Asia. In 1939–1940 another 400,000 Poles and 135,000 Germans were deported to Siberia and Kazakhstan as a direct result of the Soviet Union's incorporation of its neighboring states and various treaties signed between Germany and the USSR. There were also many smaller waves of displacement at this time, and although ethnicity was used as a main criterion for deportation, class, citizenship, and "political reliability" were still important factors in these deportations.

After the German invasion of the Soviet territories on June 22, 1941, ethnicity completely replaced class as a key factor in Soviet deportations. During 1941–1942 the entire German population of the Soviet Union, numbering over 1.2 million people, was resettled to the east, predominantly in Siberia and Kazakhstan, to prevent them from potentially collaborating with the Nazis. Yet ethnic government-enforced migration reached its peak in 1943–1944, when the Soviet government accused entire nationalities of collaborating with the Nazis against the Soviet war effort. The Soviet government deported 70,000 Karachai, 93,000 Kalmyks, 520,000

Chechens and Ingush, 45,000 Balkars, 185,000 Crimean Tartars, 12,500 Crimean Bulgarians, 10,000 Crimean Armenians, 15,000 Greeks, and finally 92,000 Meshketin Turks, Kurds, and Khemshins from Georgia. Although the official explanation for this wave of forced migration was punishment for collaborationism, many historians now believe that the true reason for ethnic deportation was the Soviet government's desire to assimilate many ethnic groups into Soviet society by relocating them far from their homes and forcing them to forget their cultures, languages, and traditions.

Some migrations, however, were semivoluntary; they did not result from any direct action taken by the government but rather from change in the political, economic, or environmental situation in the country. When the regime in Russia changed from tsarist to communist in 1917, many members of the nobility and intelligentsia found the new political order and its repressions to be intolerable. Between 1918 and 1921 an estimated 1 million to 3 million Russians fled their lands in order to seek asylum abroad. This wave of migration came to be known as the White Emigration, with the emigrants known as supporters of the whites as opposed to the Bolsheviks, or Reds. During World War II, besides state-imposed deportations, many millions of people were forced to relocate due to the coming of the Nazi occupiers to Soviet territories. Many people were evacuated from western Soviet territories to central Asia and Siberia, predominantly to Tashkent, Uzbekistan, and Alma-Ata (present-day Almaty), Kazakhstan. The Soviet Census Bureau reported 17 million evacuees during the war years; however, historians estimate that a total of 25 million people moved around the Soviet Union between 1941 and 1945 as part of evacuation attempts. At the war's end, many more people moved around after their demobilization and repatriation.

Overall, in the Soviet Union from 1918 to 1945, 12 nationalities (Germans, Karachai, Balkars, Chechens, Ingush, Kalmyks, Crimean Tartars, Poles, Armenians, Greeks, Finns, and Bulgarians) were subjected to wholesale or partial deportation, numbering roughly 2 million people. At least 30 million more became subject to forced migration due to government-induced

political cleansings, economic factors, and war-related displacement. As such, as many as 35 million to 55 million people in the Soviet Union fell victim to forced or semi-involuntary migrations during 1918–1945.

Ethnic and Forced Migrations: Jews

While much of the historical literature on twentieth-century anti-Semitism focuses on the Holocaust and Nazi Germany, in the period from 1900 to 1945, many pogroms and armed attacks on Jewish communities were enacted by tsarist (later Soviet) and Polish authorities, primarily during the interwar period. The Pale of Settlement, which formed the westernmost regions of the Russian empire bordering on imperial Germany and Austria-Hungary and where the bulk of the Jews of Europe were forced to settle by tsarist authorities in prior centuries, was the scene of multiple conflicts. These ranged from state-sanctioned pogroms under the tsar to the Final Solution implemented under the Third Reich. As a sizable minority in central and eastern Europe, Jews were a convenient scapegoat for political, economic, and social instability for the various national groups seeking autonomy or control of the region.

The Pale of Settlement for Russian Jews was created as the Russian empire absorbed large Jewish populations at the expense of the former independent state of Poland in the eighteenth and nineteenth centuries. The Pale of Settlement served as a means to restrict Jewish economic potential and mobility. In the Pale, Jews were restricted to living in ghettos (specified urban areas) and shtetls (Jewish rural communities). In the early twentieth century, tsarist authorities ac-

INTERWAR LEAGUE OF NATIONAL MINORITY TREATIES—SELF-DETERMINATION

The League of Nations instituted a series of minority protection treaties for nascent central and eastern European nations born out of the collapsed tsarist, German, and Habsburg empires. The mixed populations of Czechoslovakia, Poland, Romania, Hungary, and Yugoslavia posed a problem as the newly formed nation-states sought to form a more homogenous population to adhere to the notion of self-determination. With limited success, the League of Nations sought to ensure that minorities would not be excluded from civil and political rights. The Armenian situation in Turkey during World War I, an early example of genocide and ethnic cleansing, was the extreme case of what could potentially occur. However, the League of Nations' arranged exchanges of expatriate Greek and Turkish populations in those regions was posed as a potential solution to ensure stability in the region. Given the historically mixed populations of the European "shatterbelt," these minority treaties were seen as a means to prevent the further fragmentation of the region and to ensure stability in these historical volatile regions, fraught with centuries-old ethnic hatreds.

—*Abraham O. Mendoza*

tively supported or tolerated large-scale pogroms against Jews by local peasants of different nationalities. From 1905 to 1907, large-scale pogroms took place throughout the southern regions of the Pale as a response to the botched Russian Revolution of 1905, which was partially attributed to Jewish complicity. Due to the large influx of Jewish immigration from the Russian empire, the United States responded by pressuring the tsarist government to restore order. The February and October revolutions of 1917 and the subsequent Russian Civil War unleashed a series of pogroms in which tens of thousands of Jews were killed. Given the large numbers of civilian dead, it is difficult to arrive at an exact number.

During the interwar period, the instability of the former Pale of Settlement region, which then included the newly created Baltic states, Poland, and Ukraine, led to a series of state-sanctioned policies aimed at restrictions against

Jews. In the aftermath of World War I and the subsequent conflicts that plagued eastern Europe (the Russian Civil War, the Polish-Ukrainian War, and the Polish-Soviet War), endemic pogroms were incited by all sides. Associated as supporters of the Bolshevik regime, Jews were seen as viable targets by Polish and Ukrainian nationalists. The Polish Army's actions against Jews during this period raised suspicions among Polish Jews regarding their position in relation to the Polish state. Just after the end of World War I, for example, the West became alarmed by reports of alleged massive pogroms in Poland against Jews.

In post-World War I Europe, the nations of central and eastern Europe grappled with the American-influenced League of Nations policy of self-determination, which aimed to create homogenous nations. These newly independent nation-states across the former German, Habsburg, and Russian empires, with their intermixed populations, struggled to forge cohesive national populations. At the same time, their Jewish communities struggled to maintain a Jewish identity that did not conflict with the political ambitions of self-determination of their host states and attendant persecutions. Poland instituted laws against its Jewish population to ensure compliance within the newly created Polish state; notable among these regulations were educational and employment quotas that specifically limited the number of Jews in certain professions and universities. A sizable Jewish population in large Polish cities and the countryside found itself alienated from much of the Catholic Polish population during the greater part of this period. While many Jews sought to pursue assimilation into Polish society as a way to prevent discrimination, they were still seen as suspect and foreign by many Poles.

With the emergence of Nazi Germany and its anti-Semitic ideology, European Jewry was targeted as the primary racial and ideological (given that all Jews were portrayed as potential Bolsheviks) enemy of the state. However, as the Third Reich expanded eastward into the former Pale of Settlement from 1939 to 1945, it found many willing participants in the non-Jewish population as collaborators in all phases of the Holocaust. Given the history of this region in

terms of state-sanctioned and grassroots pogroms, restrictions, and violence against Jews, it is suggested by some historians that Germany would not have succeeded to the degree that it did had it not enjoyed such a high degree of local cooperation.

Refugees as a Phenomenon

While human beings have sought safe havens to escape religious and political persecution throughout history, the legal concept of the term “refugee” has essentially emerged and developed in the twentieth century. Some of the earliest instruments of law, such as the Nansen Passport, devised to recognize refugee status and to enable flight from hardship, came into being in the first half of that century.

Between 1900 and 1945, forced population movements were mainly the outgrowth of territorial realignments across Europe and Asia due to World War I and World War II. The emergence of the refugee as a specific legal phenomenon is strictly connected with international organizations that were established to deal with the problems and status of the millions of people displaced as a result of the two wars.

In the period preceding and following World War I there were substantial uprootings of populations and population exchanges en masse. The collapse of the Ottoman empire, accelerated by the Balkan Wars of 1912–1914, among other causes, resulted in the displacement of some 250,000 Bulgarians from various countries of southeastern Europe and nearly 500,000 Turks from Greece; about 1 million Greeks from Turkey were subjected to transfer policies imposed by newly emerging postimperial nation-states. The Bolshevik Revolution of 1917 caused succes-

sive waves of flight from Soviet Russia. The ascent of authoritarian rule in Italy, Spain, and Germany that resulted in attempts to establish homogenous nation-states resting on the Westphalian ideal of *cuius regio, eius regio* (whose land it is, his religion it is) forced many to escape their respective homelands in the hundreds of thousands. Before World War II began, the number of people forced to leave their homes totaled some 30 million.

To deal with the massive number of evictions, the League of Nations founded the High Commission for Refugees in 1921 and subsequently entrusted its leadership to Fridtjof Nansen, a Norwegian explorer, scientist, and diplomat. To solve the problem of stateless persons, most of whom were Russians displaced by the 1917 revolution, Nansen devised an instrument that was later called the Nansen Passport. By the time World War II began, the document came to be accepted by 52 governments, all of which allowed its bearers to travel as refugees to an accepting country. During his tenure as commissioner, Nansen implemented methods such as voluntary repatriation and third-country resettlement that have remained viable components of the international refugee regime well into the twenty-first century. The passport and other such methods were the first tools utilized in the previous century to distinguish the refugee as a separate, legally identifiable category of human being.

Before, during, and after World War II this identification assumed a more sophisticated character with the foundation of the Nansen International Office for Refugees in 1930, the United Nations Relief and Rehabilitation Administration

in 1943, the International Refugee Organization in 1946, and the United Nations High Commissioner for Refugees (UNHCR) in 1951 and the drafting of the Geneva Convention in 1951. The war itself uprooted some 40 million people across Europe. Known as displaced persons (DPs), they included Jews, Poles, French, Ukrainians, Czechs, and others. The ongoing hostilities among China, Japan, and the Soviets in the interwar years and in the post-World War II era dislocated many in Asia. As refugee crises deepened, the institutional infrastructure devised to solve them led to the establishment of nearly definitive criteria by which to assign refugee status to specific human beings. Among other issues, these criteria—formalized in the 1951 Geneva Convention—have come to emphasize persecution as the reason for being identifiable as a refugee, unwillingness or inability on the part of refugees to return to their countries of origin, and the principle of nonrefoulement (no forced repatriation). Contemporary work by the UNHCR is still conducted to a large extent on the basis of these criteria.

■ Introduction: Travel and Technology

The revolution in transportation was an outgrowth of the Industrial Revolution. In order for industrialization to be successful, it had to be possible to transport goods quickly and inexpensively. Technical advances, notably the steam engine, led to new forms of transportation like steamships and railroads.

Those new forms of machine-powered transportation represented a revolution in the movement of people, goods, and information across water and land. Steamships and railroads transformed the world by making transportation easier than it ever had been. The next revolution in transportation, heralded by the gasoline-powered

automobile, would likewise transform the world in the twentieth century.

By the time practical steam-powered automobiles were developed later in the nineteenth century, the gasoline engine had also been developed, and the steam automobiles never established a market. Electrically powered cars were also produced as early as 1891, but batteries were not good enough to compete against gasoline engines. In Germany the mechanical engineer Karl Benz was awarded the first patent for a gasoline-powered automobile with an internal combustion engine in 1886. After successful demonstrations in France, Charles and Frank Duryea demonstrated the first practical gasoline-powered automobile in America in 1894, triggering a rush to develop marketable cars. In 1896 Henry Ford built his first gasoline-powered car and opened a factory called the Ford Motor Company to produce them in 1903. Ransom Olds then began mass-producing the Oldsmobile in 1901 with a production of 425 cars.

Two important events for the automobile industry occurred in 1908: William Durant formed the General Motors Corporation, and the Ford Motor Company introduced the Model T automobile. In 1913 Ford began assembling cars on a moving assembly line, which became a crowning achievement of the Second Industrial Revolution.

Special types of automobiles evolved into buses in order to offer flexible public transportation for those who opted not to purchase their own cars. Although a bus carries fewer people than a train, usually between 8 and 70 people, buses run on the same roads as cars and can stop for passengers anywhere along the road, which offers public transportation to many more places. The first regularly scheduled bus service started in New York City in 1905. Other large cities soon started bus routes to connect their rail and street-car lines with outlying residential areas.

Automobiles and buses moved passengers from place to place, but a solution was needed to move freight from factories and farms to ships and trains and then from the boat docks and railroad yards to customers. Even in the 1890s those two portions of freight transportation were done with horse-drawn wagons, as they had been for a thousand years. Consequently, the truck was created using the same technology as

the automobile. Trucks are manufactured in many forms: pickups, flatbeds, tractor trailers, tankers, and dump trucks. They are also designed to perform such specialized functions as making deliveries, fighting fires, towing cars, and lifting heavy loads and even for off-road uses like hauling dirt. Probably no other form of transportation is as flexible or adaptable as a truck. The first trucks were developed during the 1890s and were based on steam power or electric batteries, but they were too fragile for the roads at that time and too expensive to operate. Soon gasoline engines were adapted for trucks, and stronger bodies were made to carry heavier loads over the rough roads.

The creation of small internal gas-powered engines that proved useful for automobiles also helped spur the development of powered flight. Human flight was just a dream until the development of the airplane early in the twentieth century. Although balloons, blimps, gliders, and helicopters have been flown over the years, nothing has been as successful as the airplane.

An airplane is totally impractical without an internal combustion engine or a jet engine to power it, which made its initial development dependent on the availability of a lightweight gasoline engine to turn a propeller and pull the plane through the air. As time went by a jet engine, which is a special type of gas turbine, was developed that either turns a propeller (turboprop), pushes the plane through the air by its exhaust (turbojet), or augments the turbojet with engine-driven fans to increase their power (turbofan). Flight also required a firm understanding of aerodynamics—the science of air flowing over surfaces—which generates the lift to hold the plane in the air.

In Germany in the 1890s Otto Lilienthal began constructing and flying in gliders. In 1899 two bicycle shop owners in Dayton, Ohio, Orville and Wilbur Wright, started experiments to develop an airplane that could actually take off under its own power with a pilot on board. Over the next four years they conducted tests in a wind tunnel of their own design and built model gliders to find a way to control the plane in flight. They also obtained a 12-horsepower gasoline engine that was light enough to be used on an airplane. With the flight controls and the en-

gine, they designed and built a biplane (a plane with two wings) big enough to carry a pilot. In 1903 the Wright brothers successfully flew their plane in a field near Kitty Hawk, North Carolina. Orville made the first flight of 120 feet (36.6 meters) at roughly 30 miles per hour, but Wilbur made the longest flight, more than 850 feet (259 meters). Those two efforts were the first manned flights of an airplane that included a takeoff and successful landing.

After the Wright brothers' demonstrations, many people began to make successful flights. Better and lighter engines soon became available. Biplanes were used for dramatic dogfights during World War I and helped to train hundreds of new pilots in the process. In 1918 the U.S. Post Office began to carry the mail across the country by plane on a regular schedule, creating the first airmail service. The first truly successful airplane for commercial service was the Douglas Aircraft Company's DC-3, which entered service in 1936. The DC-3 flew commercially in the United States for many years and is even still flying today in some countries.

In order to get around size constraints at airports during the 1930s, commercial seaplanes that took off and landed in the water became available. The seaplanes, called flying boats, flew between America and Europe and to the Far East. The planes had luxurious accommodations, including staterooms, for the 36-hour trip between America and Europe. Germany tried to establish a commercial flying service using hydrogen-filled dirigibles (called zeppelins) to fly to America, but unfortunately a zeppelin called the *Hindenburg* exploded on landing in New Jersey in 1937. The *Hindenburg* explosion ended that type of commercial service.

As in World War I, military developments during World War II significantly advanced technology, including advanced airframe designs and new sources of power. In 1946 airplane manufacturers began producing commercial transports, particularly propeller-driven aircraft with four engines like the Douglas DC-6, the Lockheed Super Constellation, and the Boeing Strato-cruiser. The airplanes could fly 100 or more passengers nonstop across the continent or across the Atlantic Ocean at speeds of 300 miles per hour (480 kilometers per hour). However,

another new technology from the war, the jet engine, quickly made the propeller-driven airplanes obsolete.

In 1939 Germany first flew a jet engine-powered fighter plane that could fly much higher and faster than propeller-driven planes. After the war Russia, Great Britain, and the United States all started developing larger bombers and transports using the jet engine. In 1952 Britain flew the first commercial service using a jet airplane, the De Havilland Comet. Unfortunately, two of the planes disintegrated in the air, killing everyone on board, and the Comet was discontinued. Instead, Britain put a turboprop, the Vickers Viscount, into service to replace the Comet in 1953. In America, Lockheed developed a turboprop, the Electra, but the turboprops did not stay in service for long, as better turbojets followed quickly, although smaller turboprop planes still fly regional routes. In 1958 the Boeing Airplane Company developed the first American turbojet airplane, the Boeing 707.

—Ronald Young

Flight

The advent of flight promised many things to many people, but the changes that aircraft provided for communications and transportation were unique. Both lighter-than-air and heavier-than-air craft prophesied important social changes.

Before World War I, there were dirigibles. The new luxury liners of the sky provided opportunities for the ultrawealthy to travel in a new form of style. German Zeppelins—rigid airships manufactured by the Zeppelin Company—became the latest mode of transportation for those who could afford it. However, a number of crashes, including the infamous *Hindenburg* (LZ-129) fire in 1937, spelled doom for the future of these hydrogen-filled airships. Only very recently have lighter-than-air dirigibles made a comeback as a method of transportation.

In sharp contrast, even with a slow start, heavier-than-air craft revolutionized communications and transportation in the twentieth century. Immediately after World War I, airplanes were widely available to many daring young

► CHRONOLOGY OF AIR FLIGHT

In the decades that followed the first successful manned and powered heavier-than-air flight of Orville and Wilbur Wright in 1903, new uses and possibilities for aircraft were developed. World War I added bombing runs to a list that was to include crop dusting, mail delivery, daredevil aerial shows, government propaganda, and limited passenger and freight service. The first commercial flights were established in 1919 in Europe, but many travelers still found rail travel faster, more convenient, and less expensive. Aircraft, however, had the allure of the modern and endowed passengers, pilots, and their nations with prestige. The Soviet Union began sending “agit-flight” squadrons to its rural regions, allowing peasants to experience air flight and wonders to come, while European colonial powers also began to rely on aircraft for communication and transportation between Europe and its far-flung colonies. Below are listed some highlights of aviation history in the 1900–1945 period.

December 17, 1903—Wilbur and Orville Wright’s first successful manned engine-powered flight.

The flight lasts 12 seconds.

July 15, 1909—Louis Blériot flies across the English Channel and is a hero in France.

June 14–15, 1919—British pilot John Alcock and navigator Arthur Whitten Brown fly from Newfoundland, Canada, to Ireland. They win the Daily Mail’s 10,000-pound prize and are knighted in England.

November 12–December 19, 1919—Australian brothers Ross and Keith Smith fly from Britain to Australia along with two mechanics, Wally Shiers and Jim Bennett. Their aircraft is one of six entered in an air race. They win a 10,000-pound prize issued by the British government and are knighted.

March 30–June 17, 1922—Portuguese pilots Sacadura Cabral and Gago Coutinho cross the South Atlantic from Lisbon to Rio de Janeiro. They make stops and repairs en route.

May 20–21, 1927—Charles Lindbergh in the Spirit of St. Louis achieves the first solo flight across the Atlantic, from New York to Paris.

May 31–June 9, 1928—Australian Charles Kingsford Smith and crew complete first transpacific flight, from Oakland, California, to Brisbane, Australia.

May 5–24, 1930—British air pilot (and former typist) Amy Johnson flies solo from Britain to Australia.

1932—Amelia Earhart crosses the Atlantic solo, duplicating Lindbergh’s feat.

pilots. In an effort to capitalize on the new technology, two distinct uses for aircraft emerged. One was in the communications field, and the other was civilian transportation.

One of the first commercial uses for aircraft was communications for business documents and mail. The first use of airmail service began immediately after the war, and by the 1920s there were airmail services around the world. The benefit of airmail was the relative speed of the service as compared to rail and ship. Initially, however, the service was quite expensive, and few took advantage of the opportunity. In an effort to build support, contests were held to prove the viability and reliability of airmail. The MacRobertson Air Race (1934), for example,

brought airmail from London to Melbourne, Australia, in record time.

But airmail was not without its hazards. Bad weather and fickle machines led to delays and even crashes. In the United States airmail was privatized, but by 1934 this industry was seen as corrupt and inefficient. In 1934 the government permitted the U.S. Army Air Corps to take over airmail, but the results were disastrous. In the winter weather the army lost a number of pilots, and the service was once again given to civilian contractors. Airmail became a staple of business contracts and eventually grew into a necessity for ordinary people. The pace of life—and of communication—reached new levels, and until widespread

use of the telephone, airmail was the preferred method of communication.

The second use for flight became even more widespread. Flight for passenger travel took off in the interwar period. From business travelers to fare-paying passengers, people took to the skies with the promise of shorter travel times in luxurious settings. The demand for commercial travel was highest in the United States, where vast distances separated the commercial centers of the Northeast from the Midwest and the West Coast. With the traditional vacation spots in Florida already established and with an increasing interest in Hawaii, Americans were perfectly suited for the development of long-distance air travel. One of the first recognized airlines was Aeromarine Airways, which in the 1920s offered flights to the Caribbean from the U.S. mainland. Whereas the Europeans had integrated rail networks, the geography of North and South America facilitated the growth of commercial airliners and airlines.

By the 1930s, several airlines were in operation around the world. Led by the Americans and Europeans, fare-paying passengers relaxed in luxury as they traveled the skies. Interestingly, the Europeans focused more on speed, primarily because of the short distances in continental Europe, whereas the Americans focused on range and reliability. With these industrial prerequisites, it was no accident that by 1939, with the approach of World War II, the Americans were the world leaders in heavy four-engine bombers, and the Europeans, especially the Germans, French, and British, were much more advanced in high-speed fighter technology. Peacetime commercial aviation technology evolved quickly into wartime military weapons systems.

During the 1930s, commercial aviation technology advanced to include monoplane designs, retractable landing gear, cowled or aerodynamically covered engines, and substantial improvements in engines, instruments, and fuels. By the late 1930s, there were two completely independent programs, one in Germany and the other in Britain, to develop gas turbine (or jet engine) aircraft. The German jet designer Hans von Ohain commented after an especially rough ride in a Junkers Ju 52 triengine airliner that flight needed to be more “elegant,” and he set out to design a

quieter, smoother engine to power aircraft to higher speeds at higher altitudes.

From the military technology of the war emerged the civilian technology of the postwar period. Commercial airliners adopted jet technology for efficiency and speed, and passengers began to use the commercial skies ever more frequently. The airliner and commercial aviation became a staple of the industrialized world’s vacationing population as interest in travel grew with a corresponding increase in discretionary funds in the average Western household.

Throughout the first half century of flight there remained two distinct but often intermixed roles for civilian aviation: communication and transportation. Aircraft became the new form of transportation for both cargo and passengers and subsequently revolutionized both the communications and transportation industry.

The Automobile to 1945

Few modern technologies have had greater economic, political, social, and cultural effects than the automobile. Automobiles and their manufacture have been a source of millions of jobs and have encouraged diffuse settlement patterns, absorbed large shares of individual incomes, conferred an unprecedented degree of personal mobility, and posed a variety of threats to personal safety and the natural environment. None of this was foreseen when the first automobiles emerged from the workshops of their creators toward the end of the nineteenth century. As with many technological innovations, the automobile had a number of precursors that turned

➤ AESTHETICS AND THE AUTOMOBILE

Although most automobile owners probably would not admit it, the styling of a car has been a major influence over their choice of an automobile. During the first decades of the automobile industry, little conscious thought was given to a car's overall appearance; just getting it to work reliably was challenge enough. By far the largest-selling car of its era, the Ford Model T, was an ungainly looking thing that famously came in "any color you wanted as long as it was black." In the early 1920s General Motors began to challenge Ford's position as the world's largest automaker and in 1927 took a major step in that direction when it hired Harley Earl (1893–1969) to head its newly created Art and Color Section. Earl had designed custom bodies for luxury automobiles in California, and his influence soon resonated through General Motors. He was not a talented draftsman, but he had a keen eye for style. As he put it, his stylistic goal was "to lengthen and lower the American automobile, at times in reality and always at least in appearance." For many years General Motors cars had the most eye-catching designs, although some of the corporation's stylistic innovations such as wraparound windshields, two-tone paint jobs, tailfins, and an overabundance of chrome trim may seem a bit ridiculous today.

out to be dead ends. In France, Nicholas Cugnot built two self-propelled steam-powered vehicles between 1765 and 1770, and Oliver Evans in the United States used steam to propel an amphibious dredger that may have traveled under its own power in Philadelphia in 1805. But the true ancestors of today's automobiles were built in Germany. In 1885 Gottfried Daimler (1834–1900) and Wilhelm Maybach (1847–1929) built a two-wheeled vehicle powered by a gasoline engine, and in the following year Carl Benz (1844–1929) built a three-wheeler that may be considered the first automobile. Both vehicles used a four-stroke internal combustion engine, a design that had been created by Nicolaus Otto (1832–1891) in 1876. Although early electric and steam-powered cars had their virtues, cars with internal combustion engines went on to dominate the industry.

Although Germany can lay claim to being the birthplace of the automobile, the center of the industry soon passed to France, where firms like Peugeot, DeDion-Bouton, and Panhard produced cars at a price that adventurous members of the upper middle class could afford. France's lead was short-lived, however, as in 1904 the United States became the world's largest producer of automobiles. Being the world's largest producer meant manufacturing about 20,000 cars in that year. Cars were far from being an essential consumer good; they were instruments of fun and adventure rather than utilitarian means of transportation. Continual improvements during the first decade of the twentieth century made automobiles a more practical proposition, but their high price limited their market. Many manufacturers addressed this drawback, but none was as successful as Henry Ford (1863–1947) and his outstanding creation, the Model T. Ford was determined to build what he called "a car for the great multitude." This he was able to do by insisting on the use of specialized machinery, rigid standardization, and interchangeable parts. In 1913 his firm began to experiment with the use of an assembly line, and over the next few years this labor-saving system allowed him to slash production costs. Lowered costs allowed lower selling prices that put a Model T within the reach of millions of people who had not been able to afford a car. So successful was this strategy that by the early 1920s half of the cars on America's roads were Model Ts.

Ford thought that his Model T would continue in production for many more years if not decades, but automotive technology and public tastes were not standing still. The firm that was best able to exploit the rapidly changing automobile market was General Motors (GM). Founded by William C. Durant (1861–1947) in 1908—the same year that the first Model T rolled out of Ford's small factory—GM offered a range of automobiles that catered to every income niche. Equally important, GM set up a lending agency that allowed customers to buy cars on credit, while Ford still insisted on cash up front. Durant was an erratic manager, however, and in 1920 leadership of GM passed to Alfred Sloan (1875–1966), who emphasized styling and instituted the annual model year as a means of inducing

customers to buy a new Chevrolet or Oldsmobile even though there was plenty of useful life left in their car. In 1927 Ford finally replaced the Model T with the more technically advanced Model A, but by then it was too late, as GM dominated car sales in the United States for many decades to come.

Ford and GM through its subsidiaries Vauxhall and Opel were important manufacturers in Europe as well. A plethora of European firms such as Renault, Fiat, and Morris also contended for a share of the market that was considerably smaller than that of the United States. Many firms attempted to build an affordable car in order to expand the market. One of the most notable was the Volkswagen (or “People’s Car” in English; also known as the VW), which was created at the behest of Adolf Hitler. Thousands of Germans paid into a regular payment plan that was supposed to culminate in the ownership of a new VW, but they never got their car, as only a few prototypes were produced prior to the start of World War II.

Although production of the VW failed to meet expectations, Germany took the lead in highway design and construction with the first of its autobahns. By contrast, the United States had been struggling to develop an adequate highway system for its large car population. The shortcomings of American roads and highways had been highlighted in 1919 when a fleet of U.S. Army trucks needed 56 days to travel from Washington to San Francisco, averaging only 50 miles (80 kilometers) a day as they slogged through mud, dust, potholes, and ruts. Some help came in the form of the Federal Highway Act of 1921, and a few New Deal projects carried out by the administration of Franklin Roosevelt improved infrastructure, but the Great Depression of the 1930s was a bleak one for the automobile industry. Although the number of miles driven actually increased, car sales never rebounded to their 1929 peak. Instead, the American automobile industry took on a new and vital role as the United States entered World War II in 1941. Automobile production came to a virtual halt as the industry was transformed into a great arsenal of democracy when it became a major supplier of tanks, airplanes, engines, ordnance, and other necessities of modern warfare.

By 1945, economic depression and war had taken their toll on the American automotive fleet. At the same time, Japan and the devastated countries of Europe were about to embark upon an economic boom that would put automobiles within the reach of hundreds of millions of people. The great postwar expansion of automobile ownership was about to begin.

The Panama Canal

The Panama Canal was built by the U.S. government during 1903–1914 following a failed attempt by the French in the 1880s. Cutting through the Isthmus of Panama (or Isthmus of Darien), the canal connects the Pacific Ocean to the Caribbean Sea. A remarkable engineering feat and a prime example of U.S. president Theodore Roosevelt’s Big Stick diplomacy, it has been a crucial waterway for commercial and military shipping and remained under U.S. control until 1977. The Isthmus of Darien is only 50 miles (80 kilometers) wide, but it features difficult terrain, rain forests, heavy rainfall, and disease-bearing mosquitoes. The first European explorer to cross the isthmus was Vasco Nuñez de Balboa (1513) en route to his historic first glimpse of the Pacific Ocean. Under Spanish control, Panama soon became a transit point for shipments of Peruvian bullion that were transported on mule trains across the isthmus before the final sea voyage to Cuba and Spain. Spanish king Charles I (1516–1556) considered digging a canal, but a survey showed that the undertaking was beyond the technology available at the time. During the California Gold Rush

era, land crossings at Guatemala, Nicaragua, and Panama to link shipping lines became a popular travel route to California's Mother Lode terrain. In 1855 when Panama was a province of an independent Colombia, a narrow-gauge railroad financed by U.S. capital opened. The first attempt to dig a canal was led by Ferdinand de Lesseps, the French diplomat who led a similar project to completion in Suez (1859–1869). De Lesseps's private company obtained a 99-year concession from Colombia in 1878 and, after purchasing the American-owned railroad in 1880, began excavation the following year.

The French effort was undermined by a variety of factors. First among them was the decision to build a sea-level canal. Although this decision eliminated the need for complicated locks, it greatly increased the scope of the excavation. Furthermore, rainfall and mudslides undermined the capabilities of the steam-powered shovels. Tropical fevers also decimated the workforce, and by 1889 the endeavor had lost 25,000 workers and had only completed 10 percent of the work. The company also ran out of funds, ruining small shareholders and sparking a massive scandal in France, as the company had

bribed politicians and journalists to keep its financial troubles secret.

Meanwhile, U.S. interest in a canal increased. The settlement of California and other western states had escalated the need for east-west commerce, which the transcontinental railroads could not fully meet. The Spanish-American War (1898) established the strategic need for a quick route from naval bases in California to the Caribbean. Inspired by the 1823 Monroe Doctrine and Alfred Thayer Mahan's *The Influence of Sea Power upon History* (1890), U.S. politicians such as Roosevelt concluded that such a canal, if built, should be under U.S. control.

U.S. politicians and engineers considered two other routes besides Panama: (1) the Isthmus of Tehuantepec in southern Mexico and (2) Nicaragua. The latter was long a U.S. favorite because the San Juan River and Lake Nicaragua could be made use of. But Philippe Bunau-Varilla, an engineer who had worked on the French venture and hoped to profit from his shares in the bankrupt Panama Canal Company, convinced President Roosevelt to opt for Panama by arguing that a Nicaraguan route was longer and dangerously close to volcanoes. The U.S. government bought the company's assets in Panama (including the railroad) for \$40 million.

The Hay-Herran Treaty (1903), named after U.S. secretary of state John Hay and Colombian chargé d'affaires Tomas Herran, specified that Colombia would grant the United States a renewable 100-year lease on a six-mile zone that excluded Panama's main cities of Colón and Panamá City for a one-time payment of \$10 million and a yearly \$250,000 rent. The Colombian Senate refused to ratify the treaty, however, and Roosevelt conspired with Panamanian nationalists to incite a rebellion in Panama. A U.S. naval blockade prevented Colombia from rushing in reinforcements and allowed Panama to obtain its independence in November 1903. Bunau-Varilla, now an ambassador, subsequently signed the Hay-Bunau-Varilla Treaty (1903) under which Panama accepted the same financial compensation previously rejected by Colombia but had to grant the United States a larger zone, 10 miles (16 kilometers) wide, in perpetuity (the United States also obtained partial authority for police and sanitation in Colón and Panama City).

Construction of the Panama Canal, about 1910. The canal revolutionized the possibilities for the international movement of people and trade goods. (Library of Congress)

Panamanians objected, to no avail, that the treaty had been negotiated by a nonnational.

The U.S. government then focused on solving the epidemiological problems that had plagued the French effort. Dr. Carlos Juan Finlay of Cuba had rightly posited in 1881 that one species of mosquito (the *Stegomyia fasciata*) transmitted yellow fever. In 1897, British physician Ronald Ross had identified another species of mosquito, *Anopheles*, as the carrier of malaria. Dr. William C. Gorgas led a massive sanitation effort that drastically reduced yellow fever and malaria cases in Panama by destroying mosquito breeding grounds.

The work itself, led by chief engineers John F. Wallace, John F. Stevens, and Lt. Col. George W. Goethals, began in earnest in 1904 and lasted until 1914. Instead of the sea-level design advocated by de Lesseps, the U.S. design centered on a dam built at Gatún, creating an artificial lake that allowed ships to sail through the isthmus while minimizing excavation at the highest point of the isthmus (Culebra Cut). Starting from Colón on the Caribbean side, ships were to be raised by three pairs of massive locks (110 feet wide and 1,000 feet long) up to the height of Gatún Lake, sail through the lake and the high part of the canal, and then be lowered through two pairs of locks (Pedro Miguel) and then another pair (Miraflores) to the Pacific Ocean. Other improvements included heavier machinery and better use of the

existing railroad to haul debris away from the construction site.

The Panama Canal was completed under budget in 1914 at a total cost of \$365 million. The canal was protected by permanent U.S. bases and occasional military interventions, the last one in 1989–1990. Under the Panama Canal Treaties, signed in September 1977 by U.S. president James E. Carter and Panamanian leader Omar Torrijos, the United States agreed to give the canal to Panama in 2000 while retaining the right to intervene militarily should neutral access to the canal be impeded. More than 14,000 ships transited the canal in fiscal year 2005.

Needs of Urbanization

In the first half of the twentieth century, the expanded urbanization that occurred throughout much of the developed world was characterized by the establishment of transportation, sanitation, and electrification infrastructures; steel construction in architecture; and the expansion of suburban and urban housing projects. The urbanization that occurred in the developing world, while mirroring some developments in the West, was not to the same degree due to their economic and political subservience to Europe. However, most of these changes were made in order to address the economic, social, and political needs created increased urban populations in a vastly changing urban landscape. Due to the increased rates of internal migration from the country and external immigration to conurbations in the West, state initiatives drove many of these infrastructural and architectural projects to fulfill the needs of the urban populace, which had expanded rapidly vis-à-vis rural populations.

Cities in Europe (mostly in Britain, France, Germany, and regions in Italy and Austria), North America (the United States and Canada), and Oceania (Australia and New Zealand) experienced massive waves of internal migration due to the rapid rate of the Second Industrial Revolution, which contributed to the expansion of electricity, chemicals, and consumer goods in their respective societies. Moreover, the growing affluence of their middle classes led to the expansion of suburban and exurban (areas outside suburbs) housing in areas surrounding the center of the city (downtowns or central business districts). This necessitated the construction of reliable public transportation to and from the city center to the suburbs, a slow transition from horsecars to subways and trolley cars. However, the exodus of the well-to-do to the wealthier concentric areas that surrounded the city centers were filled by rural migrants or, in the case of the “neo-Europes,” vast communities of immigrants. In the case of the United States, the internal migration of African Americans from the Jim Crow South to northern cities in the first half of the twentieth century also shaped the urban settlement patterns of major cities such as Detroit and Chicago. In the Soviet Union, particularly during the Stalinist Five-Year Plans of the interwar period, cities such as Magnitogorsk were established next to vast centers of industrialization.

As a result of this rampant growth particularly in the interwar period, municipal, regional, and national governments took a more proactive stance at subsidizing city infrastructure in the forms of creating sanitation, transportation, and electrical infrastructural improvements. Major cities like London, New York, Paris, Berlin, and Tokyo, which had experienced massive growth in the late nineteenth century, grew immensely in terms of suburban and exurban developments, which necessitated more investment in the installation and expansion of existing trolley lines, subways, sidewalks, paved roads, electric grids, telephone lines, gas lines, municipal dumps, and water and sewage systems. Often, these improvements were done by the municipal governments at public cost or through private firms (utilities monopolies in the United States) at public expense and regulation. Moreover, it became a government prerogative to en-

sure that the needs of urbanization, such as expansion, were planned and executed under state auspices to ensure compliance of building codes and sanitation standards. In the midst of this expansion, cities absorbed outlying suburbs and adjacent towns and rural communities outside of the city walls in the European context.

While municipal governments provided the means to develop urban conglomerations during this period through the establishment of infrastructural improvements based on technological advancements developed from the Second Industrial Revolution, commercial considerations also had a significant impact. City centers (central business districts, or CBDs), as the commercial and financial centers of business, retained their importance as the hub of city life (characterized by steel-framed high rises and modernist architectural designs in the United States), while external regions also developed their own retail and commercial establishments closer to their residential communities. Wealthy communities developed shopping centers with consumer goods geared toward their respective residents, while poorer neighborhoods retained their smaller, more localized shops and specialized services geared to the working and poor classes (especially in Berlin, Chicago, and San Francisco).
